SPECIAL NOTICE.

This issue of "The Chemical Engineer" combines the February and March numbers, all subscriptions being extended accordingly. The April issue will be published during the first week in that month, and thereafter the publication date will be on the first of each month.

BUSINESS CHEMISTRY.

One of the great needs of industrial chemistry in America is the development of the business sense of the chemist himself. Laboratory results must be presented to the business world in a way so as to inspire financial confidence. The tendency to look for quick returns has been altogether too great. Oftentimes years of careful research are necessary before tangible financial results can be obtained, and the work of the industrial chemist must be such as to command the necessary financial backing during those years. It is of vital importance that he be able to present his technical knowledge in terms which will be understood by the man of business.

In foreign countries, particularly in Germany, research work has been backed to the ultimate limit, not only by the Government, but by private capital. Similar work for the future is being done to a certain extent in this country, but only to a very limited degree. During the next few years the economic conditions which will undoubtedly develop will place a premium on careful, painstaking research work—work which will be sure rather than showy. We have just begun to realize what is meant by the elimination of waste and the utilization of wastes. The chemist and the efficiency expert must labor side by side.

If we are to enter into the World War, there will be plenty of work, vitally important work, for the American chemist, but when the war ends his place in the business fabric of this country will be of even greater importance.

ULTRA VIOLET LIGHT.

Its Application in Chemical Arts.

By Carleton Ellis and A. A. Wells.*

This Is the First of a Series of Articles Dealing with Investigations Conducted by the Writers Into the Possible Applications of Ultra Violet Light, and the Results Obtained Following the Exposure of Various Bodies to the Action of Its Rays. In the Present Article the Work of Other Investigators in This Field is Discussed. Part II Will Appear in the Next Issue.

Introduction.

DURING recent years the development of lamps adapted for the production of ultra-violet light have made possible new types of apparatus yielding powerful ultra-violet rays, thus placing at the disposal of the chemist the means for subjecting various inorganic and organic bodies to the action of this highly actinic form of light under various conditions. The result has been that in the last few years a large amount of research has been carried out in this field, some of which is of an extremely interesting character, leading directly to certain practical applications or indicating the possibility of such applications of ultra-violet light

It is the purpose of the present article to discuss a number of these applications and also to embrace a synopsis of the greater part of the work that has been done in this field. The result of investigations conducted in this laboratory in connection with the exposure of certain organic bodies to ultra-violet light will be briefly discussed.

The first portion of the paper is devoted to a general review of the work heretofore carried out on the chemical effects of ultra-violet light.

PART I

METALS AND THEIR COMPOUNDS.

Jacquier (British Patent 17,790, Aug. 2, 1913) describes a process of *precipitating metals* from solutions of their salts by treatment with artificial ultra-violet rays in the presence of aluminum. The process may be assisted by sunlight. Mercury vapor lamps are suspended between aluminum plates in the tank containing the solution to be treated.

Svedberg (Ber. 1909, 42, 4375-4377) has succeeded in preparing *colloidal solutions of metals* by the application of the observation of Lenard and Wolf (Ann. Phys. Chim., 1889, 37, 443) that certain substances, especially metals, are disintegrated when exposed to ultra-violet rays. Pieces of metal, the surfaces of which had been carefully freed from oxide, were placed in a shallow dish containing a dispersion oxide medium, and exposed to the rays from a Heraeus quartz mercury arc lamp at a distance of a few centimeters. After a few minutes colloidal solutions were obtained from silver, copper, tin and lead, but platinum, aluminum and cadmium remained practically unaffected. The action was especially marked in the case of lead, which yielded a colloidal solution in ethyl alcohol, and a milky liquid, probably containing colloidal lead hydroxide, in water. Experiments with silver and lead in water, ethyl alcohol, isobutyl alcohol, ether, acetone, ethyl acetate, and amyl acetate showed that the nature of the dispersion medium had a great influence on the results. It is possible to prepare solutions by this method, the colloidal particles of which are very small, and of practically uniform size.

Following Svedberg's observation that metals are disintegrated at the surface and yield colloidal particles when covered with water or alcohols and exposed to ultra-violet rays, *Kimura* (Kyoto. 1913, 5, 253) describes experiments, chiefly with *silver, copper* and an *alloy of cadmium* 90, *antimony* 10 per cent. In a vacuum no corrosion takes place, in air there is a very slight corrosion, in oxygen somewhat more, and in water strong corrosion, under the influence of the rays. The mechanism of the action is discussed and photomicrographs of the corroded surfaces of the metals are given.

Experiments with Silver.

Nordenson (Kolloidchem. Beihefte 7, 110-36, 1915) continued the experiments of Svedberg. A plate of *silver* was immersed in alcohol and exposed to ultra-violet light and the loss in weight determined from time to time. No quantitative relation between the colloid formation and the time and temperature could be established owing to experimental errors. A qualitative investigation of the formation of colloids of metals when immersed in water, alcohol and other solvents and exposed to ultra-violet, Roentgen or radium rays was continued. It was found that the action of Roentgen and radium rays was similar to, but weaker than that of ultra-violet rays. Silver gave a metallic colloid. *Gold, platinum, iron, cobalt, nickel, chromium, manganese* and *bismuth* did not form colloids. *Copper, mercury, zinc, lead* and *tin* gave colloidal formations, but their nature could not be established. Because of the easy oxidation of the metals it could not be determined whether or not aluminum, magnesium and cadmium formed colloids. On immersing pure silver in pyridine or benzene no colloid was formed, but in ethyl alcohol, methyl alcohol, acetone and water the metallic colloid was formed and identified. The colloid formation is due to the activity of the rays in forming hydrogen peroxide which attacks the metal, forming an oxide or hydrate, which in turn is dissolved in the crystalloid form, and is then reduced to metallic colloid by the reducing action of the light rays. This could be substantiated in that if a piece of silver is immersed in a 0.01 per cent. hydrogen peroxide solution and the resultant solution treated with a reducing agent colloidal silver is formed. The other metals which are more easily oxidized (copper, mercury, zinc, lead and tin) are similarly attacked by hydrogen peroxide and the reaction accelerated by the light, but a metallic colloid is not formed.

*All rights of publication in book form reserved by the authors. Consulting Chemists and Chemical Engineers, 92-98 Greenwood Ave., Montclair, N. J.

There appears to be a difference of opinion in regard to the effect of ultra-violet rays on colloids. (Zeit. angew. Chem. 1914, 18, No. 2.) It has been stated by Wiemarm that exposure to ultra-violet light causes the size of the particles of colloids to be reduced.

FORMATION OF OZONE FROM OXYGEN.

Fischer and *Braehmer* (Ber. 1905, 38, 2633) have published an article on the production of ozone by the ultra-violet light. One of these investigators devised a form of mercury arc lamp containing a double walled quartz vessel through the annulus of which a gas can be passed, and thus be exposed to the radiation of the arc. The lamp can be immersed in water and its outer glass casing kept cool, and a stream of water (or other cooling liquid) can be passed through the interior of the quartz tube, cooling one coating of the annulus, and hence, as the annular space is only about a millimeter across, cooling the contained gas very considerably. Through this apparatus pure oxygen, generated electrolytically from dilute sulphuric acid, was passed and exposed to the radiation from the arc. The total quantity of ozone formed during an experiment (15 minutes) was determined, and hence, from a knowledge of the quantity of gas that had passed, the percentage by weight in the ozonized gas was known.

The results showed that without any cooling, when the temperature rose to 270°C., no ozone was formed. Cooling the gas by water, increasing its speed while maintaining the temperature constant at 15°C., or lowering the temperature, increased the yield of ozone. Under constant conditions of cooling water, by increasing the current through the lamp from 2 to 6½ amperes, the yield was increased, but further rise of current diminished it, no doubt because of the rise of temperature which it caused. Increase of the oxygen stream corresponding to a rise from 2 to 4 amperes in the generating vessel nearly doubled the yield of ozone, but slightly decreased the percentage in the issuing gas. The effect of moisture in the oxygen was examined, but no conclusions on the matter were drawn. The experiments indicate that the conversion of oxygen into ozone by ultra-violet light is opposed by the decomposition of ozone into oxygen, the speed of which reaction increases rapidly with rise of temperature. These experiments support the view that the production of ozone in the Siemens tube is due to the influence of ultra-violet radiation.

Regener and *Fischer* (Handbuch der Diochemischen Arbeitsmethoden, Abderhalden, Vol. IV, 834) have observed that when working with ultra-violet light it should be remembered that ozone is developed and that reactions may be brought about because of the presence of ozone.

MISCELLANEOUS ORGANIC AND INORGANIC COMPOUNDS.

Per-acids (British Patent No. 16,849, July 22, 1913) are prepared by treating aldehydes with oxygen, or oxygen containing gases at low temperatures, preferably with the exclusion of injurious impurities such as water and manganese compounds. The reaction is facilitated by the use of chemically active rays. On allowing per-acetic acid, obtained from acetaldehyde, to attain room temperature, it is decomposed by the remaining aldehyde into acetic acid. The per-acids may be used to prepare hydrogen peroxide.

From results which have been shown previously that *xylene* mixed with an aromatic nitro-hydrocarbon contained more active oxygen after exposure to light and oxygen than pure xylene so treated. *Suida* (Ber. 1914, 47, 467-472; Monats. Chem. 1912, 33, 1268) has found that the presence of a nitro-compound reduced the total yield of oxidation product, but that considerable quantities of toluic aldehyde were present. Thus in the presence of a nitro-hydrocarbon the less stable products of oxidation (aldehydes and peroxides) remained, while the pure chemical reaction (the decomposition of these primary products to the next higher and more stable stage of oxidation) was delayed. It was possible by cooling in carbon dioxide and ether to bring almost to a standstill the decomposition of the benzene hydro-peroxide (formed from benzaldehyde by the action of ultra-violet light). The product of the primary auto-oxidation process could not be isolated, as it decomposed into benzoic acid within a few minutes after removing it from the cooling mixture.

Photochemical Reduction of Ketones.

Boeseken and *Cohen* (Wetenschappen 23, 765-86, 1914) studied the photochemical reduction of *ketones* by anhydrous alcohol, both by direct sunlight and light from a quartz mercury arc lamp. Five grams of the ketone in 50 cubic centimers of dry alcohol sealed in ordinary glass tubes was exposed to the light. Reduction in this manner gave only pinacols. The reaction velocity is independent of the concentration of ketone and proportional to the concentration of the alcohol and may be represented as follows: 2 ketone + alcohol = pinacol + aldehyde. The temperature coefficient was very small. The rate of pinacol formation depends greatly on the alcohol employed, methyl alcohol and allyl alcohol acting slower than other primary and secondary alcohols; also on the ketone, benzophenone being reduced more rapidly than other ketones. Many were not reduced at all. The relative rates in different alcohols are the same. The active light in the ketone reduction lies between 400 and 430, and probably at or near the rays 404.7 and 407. The relation of the rate of pinacol formation is the same in sunlight and in mercury light. When two ketones are present simultaneously, one absorbs a part of the rays needed by the other; this is also evident when the light, after passing through one, is allowed to act on another. This interference is greater than would be expected.

Schmitz & Co. (British Patent No. 3,053, Feb. 5, 1914) have prepared *esters of phenol* homologues, halogenized in the side chain by treating the esters alone or in suitable solvents (such as carbon tetrachloride) with halogen in the presence of light, especially from a source rich in ultra-violet rays. Halogen carriers may be employed if necessary.

Winther and *Oxholt.Howe* (Z. Wiss. Phot. 14, 196-212, 1914) have made a study of the photochemical decomposition of *iron oxalate, succinate, tartrate, citrate* and *acetate* for short wave lengths, chiefly ultra-violet. The reaction velocity is approximately constant throughout the whole change. The "quantum-sensitiveness" is greater than unity, showing a catalytic light reaction. In terms of unit quantity of incident light, the sensitiveness at a given concentration increases as the absorption co-efficient of the solution decreases. This may be ascribed to the existence of two substances, one photosensitive, the other insensitive and causing most of the absorption. The per cent. effect of the incident light also increased with increasing dilution.

Kailan has published a pamphlet (Institut für Radiumforschung, Wein. 1913), in which he discusses the decomposition of various *organic acids* by the ultra-violet light, the action of the rays on *amyl alcohol* and on *iodine* and *iodides* in various strengths of acid solution.

Work of Berthelot and Gaudechon.

Berthelot and Gaudechon (Comptes. rend., 1910, 150, 1169) have made a study of the chemical effects of the ultra-violet rays on a variety of substances. *Acetylene, ethylene, cyanogen* and *oxygen* show in every case a diminution in volume owing to polymerization, no other chemical change being observed. Acetylene is converted into a yellow solid (more readily under reduced pressure or when mixed with an inert gas such as hydrogen or nitrogen); ethylene gives a liquid polymer with the odor of rancid fat; cyanogen is converted into paracyanogen; and oxygen to a small extent into ozone

Cyanogen is oxidized practically completely to carbon dioxide and nitrogen, a mixture of *ammonia* and *oxygen* yields nitrogen and water, but free *hydrogen* is not oxidized appreciably by oxygen at the ordinary temperature under similar conditions. By the action of ultra violet rays on mixtures of acetylene and ethylene respectively with oxygen, some formic acid is produced. (Comptes. rend., 1910, 150, 1327.)

Air or mixtures of nitrogen and oxygen produced no appreciable effect. *Nitrous oxide* alone or mixed with oxygen produced nitric acid. *Sulphur dioxide*, alone or mixed with oxygen, yielded free sulphur and sulphuric acid. (Comptes. rend., 1910, 150, 1517.)

The modes of decomposition are classified according to the constitution of the compounds—i. e., alcohols, aldehydes, ketones and acids. (Comptes. rend., 1910. 151, 1349.)

Solutions of *Ammonia* (Comptes. rend., 1911, 152, 522) in the presence of pure oxygen or of air when exposed at a temperature of 35°-50°C., for from 3 to 9 hours at a distance of 3-6 cm. from a lamp of 110 volts, are oxidized to nitrites. Nitrates were in no case formed. *Ammonium salts* were also oxidized to nitrites, the reaction being slower in the cases of the sulphate and chloride than in that of the carbonate. Urea was also converted first into ammonia and then into nitrite. Other organic nitrogen compounds—e. g., *ethyl* and *methylamine, guandine, hydroxylamine, acetamide, acetonitrile*, etc., behaved similarly. Stress is laid on the close analogy between the effects of the rays and the action of enzymes. The rays are further able to convert *nitrates* into nitrites, and to decompose concentrated solutions of *ammonia nitrite* with liberation of nitrogen.

Explosives.

Nitroglycerine (Comptes. rend., 1912, 154, 201), 0.10 grm. after 30 minutes' exposure at 20 mm. gave 1.32 c.c. of gas containing carbon dioxide 24, carbon monoxide 10.5, nitrogen 17.5, nitrous oxide (N_2O) 8.5 and nitric oxide (NO) 39.5 per cent. Some nitric oxide was also destroyed in attacking the mercury in the testing apparatus. The high percentage of nitric oxide explains its presence in the products of decomposition of powders containing nitroglycerine. A piece of nitrocellulose (collodion) 15 by 51.6 mm., after 2 hours at 20 mm., gave 0.87 c.c. of gas, the percentages of its constituents in the same order as above being 25.5, 19.5, 39, 7, 9. Collodion, though less nitrated than the French service smokeless powders, decomposes more readily and evolves a notable amount of nitric oxide. This shows the use of the gelatinization adopted for this powder and of the stabilizers incorporated in it. Comparison of two powders of the same age and make stabilized by amyl alcohol and diphenylamine respectively showed that at 20 mm. (temp. 75°C.) *amyl alcohol* is the more efficient, the latter powder giving off less gas, and the gas containing a very much lower percentage of nitric oxide than the former. (As new powders of the former type do not show nitric oxide in the products of their "photolysis" the source of it in this powder, which was six years old, is no doubt the nitrosodiphenylamine formed during the slow decomposition of the powder). At 50 mm. (temp.

40°C.), on the other hand, *diphenylamine* is the more efficient stabilizer. Similar results were obtained with two more recently prepared naval powders, save that these evolved no nitrogen oxides. When the powders were treated with alkali (1 gm. with 20 c.c. of N/2 potassium hydroxide for 30 minutes at 15°) it was found that the diphenylamine powder showed less decomposition than that stabilized with amyl alcohol. A *damaged naval powder,* in which the brownish yellow plates showed whitish stripes, was examined by the lamp. At both distances the damaged parts gave off more gas than the unaltered parts, and this gas contained from 12 to 30 per cent. of nitrogen oxides, while the gas from the unaltered parts contained none.

Effects of Various Atmospheres.

The experiments (Comptes. rend., 1912, 154, 514) were repeated in oxidizing (oxygen), reducing (hydrogen) and inert (carbon dioxide, nitrogen) atmospheres. With oxygen, two-thirds of the free oxygen disappeared and added its oxidizing effect to that of the oxygen of the nitrocellulose. With hydrogen, about one-quarter disappeared, forming water and formaldehyde. With carbon dioxide much depends on the temperature; at 25°-30° C. (70-80 m.m. from the lamp) there is absorption, due no doubt to the solvents and stabilizers which are basic in their character; at 40°C. (50 m.m. distance) no change in volume occurs; at 75°C. (20 m.m. distance) there is disengagement of carbon dioxide from the powder and the final volume shows an increase. Nitrogen has no effect on the evolution of nitrogen or nitrous gases from the powder.

Heating *smokeless powders* to 110°C. for periods of from 4 to 110 hours produced no effect on their behavior under the lamp, save that due to the fact that a certain quantity of the solvent in the powder was volatilized by the heating; but no nitric oxide was produced, showing that much longer periods of heating would be needed to "age" a powder artificially.

Picric acid, like other aromatic compounds, was found to be very stable under exposure; no decomposition took place at 50 m.m. distance, and after 3 hours at 20 m.m. only a slight browning occurred and evolution of about 0.7 c.c. of gas. *Ammonium picrate* was still more stable and showed no decomposition even at 20 m.m. from the lamp.

Under the influence of ultra violet light (Comptes. rend., 1912, 155, 521) *acetylene* can be made to yield a solid yellowish polymerized product. *Ethylene* polymerizes to a thick liquid boiling above 100°C. and bearing some resembrance to caprylene. Allylene gives rise to a whitish solid. *Methane* shows no tendency to polymerize, but in the presence of oxygen it loses hydrogen and forms higher homologues of the paraffin series.

Decomposition of Carbonyl Organic Compounds.

Organic compounds (Comptes. rend., 1912, 155, 401-403) containing a carbonyl group show exceptional sensitiveness toward light. Solutions of *ketoses,* protected from the air, were found to be slowly decomposed by sunlight. One c.c. of a ten per cent. solution of dihydroxyacetone evolved 0.2 c.c. of almost pure carbon monoxide on exposure to sunlight for twelve hours. Erythrulose, lævulose, sorbose and perseulose were decomposed much more slowly, for with increase in the length of the carbon chain the photo-sensitiveness diminishes. A solution of lævulose produced only 0.54 c.c. of gas per c.c. in about two months' time. In all cases the gas evolved was almost pure carbon monoxide. The reaction which takes place under these conditions consists in the elimination of the carbonyl group and the conversion of the ketose into an alcohol containing one carbon atom less in the molecule. A similar reaction occurs under the influence of ultra-violet rays from a quartz mercury lamp, but it then proceeds much more rapidly and is accompanied by subsidiary reactions with the result that carbon monoxide produced contains some carbon dioxide, hydrogen and methane. Ketoses in the solid state are decomposed by ultra-violet rays in the same way as when dissolved in water.

Di-Saccharides.

Ultra-violet rays (Comptes. rend., 1912, 155, 1016) of relatively long wave length photolyze *di-saccharides* in two stages. In the first stage hydrolysis takes place without any evolution of gas, the second stage is characterized by a regular evolution of gas due to decomposition of the mixture of monoses produced in the first stage. The solutions remain neutral throughout the experiments, so that the photolysis of *sucrose* to dextrose and lævulose and of maltose to two molecules of dextrose is not brought about by the formation of acid in the solutions, as has been suggested.

Of the three compounds studied, viz.: acetaldehyde, ethyl alcohol and acetic acid (Comptes. rend., 1913, 156, 68), only acetaldehyde is decomposed by sunlight (wave length greater than 0.3). Light from a mercury lamp screened by thin glass which absorbs all rays of wave length less than 0.3, decomposes acetaldehyde in accordance with the equation $CH_3.CHO = CO + CH_4$. Frequently the proportion of methane to carbon monoxide actually found is somewhat less than corresponds to this equation, for the light causes polymerization of some of the aldehyde to paraldehyde, which is then photolyzed to carbon monoxide and ethane or more complex substances. These latter reactions are most readily produced by the extreme ultra-violet rays. Direct rays from a mercury lamp, without any interposed screen, photolyze not only acetaldehyde but ethyl alcohol and acetic acid. *Ethyl alcohol* is decomposed primarily into acetaldehyde and hydrogen (J. S. C. I. 1911, 1086), but usually some carbon monoxide and ethane are formed by the further decomposition of the aldehyde. By the photolysis of *acetic acid* a gas was obtained which contained 44 per cent. of carbon dioxide, 17 of carbon monoxide and 39 per cent. of combustible gases (J. S. C. I. 1910, 1081). All the results described above relate to photolysis in absence of air. In presence of water the reactions take substantially the same course, but there is a tendency toward the formation of acid products.

Verification of Law.

The law of inverse stability of compounds in relation to their increase in molecular weight has been verified by experiments on the compounds of the nitrogen and carbon groups when under illumination (Comptes. rend, 1913, 156, 1243-1245). With a large 220-volt mercury lamp an almost complete decomposition of ammonia was obtained in two hours. With *hydrogen phosphide* in a quartz tube at 20 m.m. from the lamp, decomposition was evident in a few minutes, while in glass tubes it was not quite complete in 30 min. *Hydrogen arsenide* in glass glass tubes was unaffected after two hours, but in a quartz tube a deposit of arsenic was formed in 15 seconds and decomposition was complete in 10 minutes, a mirror of arsenic being formed. *Methane* was not decomposed by the most intense illumination. *Zinc ethyl* gave zinc and pure ethane free from ethylene in 5 minutes. *Carbonyl chloride* in a quartz tube was decomposed in less than 5 seconds, but when in a glass tube no decomposition could be detected after two hours. *Sulphur fluoride* in a quartz tube was not decomposed by three hours' illumination.

The tendency of *carbon monoxide* (Comptes. rend., 1913, 157, 129-131) to form compounds under the influence of light is most pronounced with the lowest members of a series; it combines with chlorine, not with bromine or iodine; with oxygen or water, not with sulphur or hydrogen sulphide; with ammonia, not with phosphine or arsine.

Copper (Comptes. rend., 157, 129-131) also combines with chlorine, but not with bromine or iodine; with oxygen, but not with sulphur; with water, but not with sulphurated hydrogen; with ammonia, but not with phosphine or arsenurated hydrogen.

Oxides of carbon and water vapor (Comptes. rend., 1910, 150, 1690-1693) have, as stated, been made to react with each other by means of the light of the mercury vapor lamp. *Carbon monoxide* and oxygen produce a small amount of carbon dioxide, while the latter gas yields carbon monoxide when exposed to the rays in the presence of phosphorus. *Carbon dioxide* and hydrogen give water and formaldehyde (which, as is known, is capable of forming carbohydrates by successive condensations). Water can be made by the action of the rays on a mixture of *hydrogen*, and *oxygen* and *water vapor* itself is decomposed in the presence of carbon monoxide or phosphorus. *Formaldehyde* can be made directly from hydrogen and carbon monoxide, while formaldehyde is decomposed in the presence of nitrogen when exposed for several hours close to the lamp. Carbon monoxide and ammonia gas also give formaldehyde.

Photolysis of Oxalic Acid.

The photolysis of *oxalic-acid* (Comptes. rend., 158, 1791-3) consists in the primary decomposition into carbon dioxide and formic acid, followed by a secondary decomposition of the nascent acid into carbon monoxide and water by rays of long wave length and into carbon dioxide and hydrogen by waves of short length. This further shows that the radiant energy represents a lower form than thermal energy and that the frequency of vibration plays the same role in the former as does the temperature in the latter.

The photochemical effect of ultra-violet rays (Comptes. rend., 1910, 151, 395-397) is to lower the temperature of reaction, oxidations and decompositions being effected below 100°C., which otherwise are only produced at red heat, and to accelerate the reaction velocity. The reactions produced are reversible and the rays produce a high polymerizing power, *acetylene*, for instance, being converted not into benzene but into a solid polymeride. In these and other respects photochemical action resembles the chemical reactions produced in living organisms, especially in plants. Just as in plants, methyl compounds are met with much more frequently than ethyl compounds, so in photochemical reactions *methyl compounds* are easily synthesized, but the production of *ethyl compounds* is difficult and uncertain. In photochemical reactions with *ethylenic* and *acetylenic compounds* in presence of oxygen, the double and triple linkages are ruptured and simple acids formed, while in presence of ammonia cyclic compounds are formed. *Ethylene*, for example, yields first amino-ethylenes and then ring formation takes place with production of compounds of the pyrolidine and pyridine types, which may be regarded as the mother substances of alkaloids. In the case of aqueous solutions, the water also is decomposed to a small extent.

Experiments with Sugars.

The results of experiments with 10 per cent. aqueous solutions of different sugars, exposed for 10 hours at a distance of 2 c.m. from a 110-volt mercury vapor lamp, are as follows, so far as the gaseous reaction products are concerned: (1) *dextrose* gives approximately equal volumes of carbon monoxide and methane and about six times as much hydrogen; (2) *levulose* gives about ten times as much carbon monoxide as of methane; (3) *maltose* gives similar results to dextrose; (4) *sucrose* gives results intermediate between those given by dextrose and levulose. The numerical results, calculated to a basis of 100 vols. of combustible gas, are tabulated below:

	Carbon Monoxide	Methane	Hydrogen	Carbon Dioxide
Levulose	83	8	9	15
Dextrose	12	12	76	22
Maltose	12	11	77	21
Sucrose	45	8	47	16

Henry and Ranc (Giorn. form. chim. 62, 73, 1913) have found that ultra-violet rays cause the decomposition of *glycerol* with the production of formaldehyde and traces of other substances of an aldehyde nature. The decomposition takes place more readily in the presence of water.

Mathews and Elder (Eng. Pat. 11, 635, May 11, 1914) produce compounds of *sulphur dioxide* and *unsaturated hydrocarbons* by direct combination by exposing the mixed liquids to sunlight or ultra-violet light, or in some cases by heating. The examples given are the compounds with *pseudo-butylene* $(C_4H_8\,SO_2)_n$, *propylene, amlene* and *ethylene*. The butylene product is a horny or glassy, clear white solid, soluble in chloroform or tetrachlorethane and not easily inflammable. It can be used for making varnishes, transparent films, etc., and may be mixed with celluloid by first softening both with acetone. It renders the celluloid less inflammable.

Effects Upon Formaldehyde.

Pribram and *Franke* (Ber. 1911, 44, 1035) state that on exposure in a quartz vessel of a redistilled 30 per cent. solution of *formaldehyde* to light of short wave length from a mercury vapor lamp for some time, no external change can be noticed. If the resulting liquid is then distilled a white residue is left. The distillate possesses enhanced reducing properties acting rapidly on Fehling's solution in the cold. The residue when freed from formaldehyde is also strongly reducing and gives an osazone which melts at 168°C. This seems to indicate the formation of glycollic aldehyde, small quantities of which would pass into the distillate. The identification is not quite complete, however, since the melting point of the p-nitrophenylosazone is rather lower than that of the corresponding derivative of glycollic aldehyde. Control experiments with formaldehyde not exposed to ultra-violet light show no evidence of condensation. Coincidently with this (Monatsh. Chem., 1912, 33, 415) formic acid is produced along with a small amount of higher condensation products. The amount of acid formed is determined by the length of the exposure to the rays. Carbon dioxide and monoxide, hydrogen and methane are also produced in lesser degree. The oxygen necessary for the acid formation does not result from decomposition of the water present nor from ozone produced by the action of the rays upon air which may be present, since the formation is in no way hindered if air is excluded.

Stobbe (Ber. 47, 2701-3, 1914) states that *styrene* has never been completely transformed spontaneously into pure metastyrene, indicating that equilibrium is established between the polymerizing and depolymerizing reaction in such a homogeneous system. Solutions seemed better adapted for the study of this problem than the substances alone. Accordingly 8.58 per cent. solutions of styrene in benzene were kept in the dark on one hand and for two months in sunlight on the other; the first remained unchanged, while the refractive index changed from 1.49257 to 1.50048. In 2.2 per cent. benzene solutions of metastyrene the index of refraction of the illuminated solution changed from 1.49888 to 1.49842. Again 5 per cent. solutions showed the following refractive index after 0, 20, 32, 95 and 230 hours illumination in uviol tubes: styrene, 1.49883, 1.49911, 1.49939, 1.49994, 1.49994; metastyrene 1.50125, 1.50125, 1.50125, 1.50116, 1.50116. The illuminated solution of styrene gave a precipitate of metastyrene with alcohol; that of metastyrene decolorized $KMnO_4$; the solutions kept in the dark did not. Similar experiments with *stilbene* in benzene indicate that the equilibrium of stilbene lies very far toward the right, while in alcohol, ether, chloroform, trichlorethylene and pyridine there is apparently no polymerization.

Hydrolysis of Sucrose.

Euler and *Ohlsen* (J. Chim. Phys., 1911, 9, 416) exposed neutral solutions of *sucrose* to the rays from a Heraeus quartz mercury vapor lamp and determined at intervals the rotatory power, amount of invert sugar and acidity of the solutions. The experiments showed that under these conditions the sucrose is hydrolyzed and the solution becomes slightly acid. A control experiment showed that the speed of the hydrolysis due to the temperature (79°C.) to which the solutions were heated by the lamp is very slow compared with that due to the action of the ultra-violet rays. The quantity of sucrose hydrolyzed is nearly as great in a 10 per cent. solution as in one of double this concentration. The rate of hydrolysis increases with the duration of the exposure, this being accounted for by the acid formed in the reaction. The formation of this acid depends on a catalyst which is present in traces in the solutions.

Bierry, Henri and *Ranc* (Comptes. rend., 1911, 152 1629) have investigated the action of ultra-violet rays from a quartz mercury vapor lamp on 5 per cent. solutions of *sucrose* at 40°C. in vacuo and 20°C. in presence of air, with and without addition of calcium carbonate. It is found that under the influence of the ultra-violet light the sucrose is hydrolyzed to an extent which is quite appreciable after 20 hours' exposure at 40°C., while if the solution is exposed for 48 hours at this temperature it is found to contain formaldehyde. In absence of calcium carbonate gas is liberated, but this is a secondary phenomenon. The gas is scarcely perceptible before 72 hours and becomes marked on the fifth or sixth day of exposure at 40°C. Of the combustible part of this gas 50 per cent. consists of carbon monoxide.

Action on Water Virtually Electrolysis.

Tian (Comptes rend., 1911, 152, 1012) states that when *water* is submitted to the action of ultra-violet rays it is decomposed into hydrogen and hydrogen peroxide; the latter, in turn, is decomposed and oxygen is liberated, the ultimate effect of the action of the rays on water being identical with that of electrolysis. The volume of the gases liberated diminished gradually—namely, from 25 cubic millimeters per hour at the commencement of the experiment to 3 cubic millimeters per hour. The gas contains only about 1 per cent. of oxygen during the first half hour; the proportion of oxygen then increased. This appears to be due to the fact that hydrogen peroxide is first formed, and only when this begins to be decomposed is oxygen evolved. When the quantity of hydrogen peroxide becomes constant (i. e., when the amount formed is equal to that which is decomposed) the liberated gas contains two volumes of hydrogen to one volume of oxygen. The decrease in the volume of the gas after a time may be due to the action of the hydrogen upon the oxygen, which has been found to take place under the influence of ultra violet rays.

The coefficient of absorption (Comptes. rend., 1911, 152, 1483) in water of the part of the light which effects this action is a constant. Hence this part of the light must consist of a single ray or of a group of rays of nearly equal wave lengths. The curve of absorption of light in water shows that these rays must have wave lengths of about 1,850 angstrom units (1 angstrom unit equals $1 \times 10 = 7$ m.m.)

Mercury Spectrum Confirms Conclusion.

In the confirmation of this *Tian* finds that the mercury spectrum contains a group of rays of wave lengths 1,846, 1,848 and 1,851 angstrom units. This spectrum also contains rays of wave lengths 1,941, 1,971 and 2,000 units. In view of the wide interval separating this group from the former and the considerable variation of the spectrum it is concluded that the decomposition of *water* is effected by the former group only, at least under the conditions of the experiments (a statum of air 5-6 c. m. thick and a plate of quartz 1 m.m. thick separated the light from the water). This view is borne out by the fact that no rays of shorter wave length than 1,846 angstrom units were found in the mercury spectrum, though the absence of such rays was not absolutely proved. The light emitted by the spark discharge between aluminum electrodes contains rays of wave lengths 1,854, 1,857.5 and 1,862 angstrom units, and also decomposes water with the formation of hydrogen and hydrogen peroxide.

From experiments on the action of ultra-violet rays on water, concludes *Kernbaum* (Farm. Polsk., 16, 71-2, 1913) that *water* must undergo decomposition. Experiments indicate that the sun rays will act on water in the same way. Distilled water free from air was put in a quartz vessel and connected with a mercury manometer and then exposed to the action of sun rays. Evolution of gas was registered after a few hours. Using Shonbein's reagent, hydrogen peroxide was detected according to the equation $2H_2O = H_2O_2$. The quantity of it is larger when the experiments are carried out in presence of air, as was shown by the blue tint of the fluid in a quartz vessel.

(To be continued in the April issue.)

POTASH PRODUCTION IN 1916 INCREASES TENFOLD

U. S. Geological Survey Estimate Indicates Production of Nearly 10,000 Tons K_2O, With Prospect of Much Greater Yield Next Year.

Statistics of the production of potash in the United States in 1916 are nearly complete, only a few of the important known producers having failed to report to the United States Geological Survey, Department of the Interior. The following preliminary estimate is believed to be approximately correct. Complete figures will be published later, when all the returns have been received.

The total production of potash salts and potash products in the United States in 1916 was close to 10,000 tons of potash (K_2O), with a net value at point of shipment of at least $3,500,000, figured at the prevailing selling prices. This is ten times the value of the production reported for 1915, but the figures submitted by many of the producers represent only a start made toward the end of 1916. The total for 1917 is therefore likely to be much greater.

The production reported to date for 1916 may be summarized as follows:

	Available K_2O (short tons).	
Mineral sources:		
Natural salts or brines..........	3,850	
Alunite and silicate rocks, including furnace dust recoveries....	1,900	
		5,750
Organic sources:		
Kelp	1,110	
Pearlash (mostly from hardwood ashes); only 23 producers have reported to date out of a list of 70 establishments said to be producing	220	
Miscellaneous industrial wastes..	1,750	
		3,080
Total production....................		8,830

The largest output has come from the Nebraska alkali lakes, but the natural saline deposits elsewhere are now just beginning to make important contributions. The figures for potash derived from alunite, of which there is only one important producer, are combined with those for available potash in cement-kiln, flue-dust, greensand, and feldspar recoveries, in order not to disclose figures given in confidence. These do not include a considerable quantity of feldspar said to have been mined and prepared for possible use for the sake of the potash it contains.

Graphite Products Increases Stock.

The Graphite Products Corporation, of Saratoga Spa, has announced an increase in its capital stock from $30,000 to $150,000.

THE COLORIMETRIC TEST

for

The Determination of Organic Impurities in Sands

by

Prof. Duff A. Abrams and Oscar E. Harder*

The Danger from Organic Impurities in Sands Intended for Use in Mortar and Concrete Led the American Society for Testing Materials to Finance an Investigation to Develop a Reliable Test—A Report on Experiments Carried on at the Lewis Institute to Date, Which Seems to Favor the Abandonment of the Combustion Method and the Loss-on-Ignition Method, and the Adoption of Colorimetry, Is Here Given.

INTRODUCTION.

During the past few years the subject of impurities in sands for mortar and concrete has been receiving rapidly increasing attention from testing engineers and inspectors. Experience has shown that on account of the presence of impurities certain natural sands do not give satisfactory results when used in concrete, and many failures and much inferior work have been attributed to impurities in the fine aggregate. However, when it comes to determining before the sand is used in construction or subjected to tests in mortar, whether or not the sand is suitable for fine aggregate, there has been no well-established criterion regarding the impurities. Practically all specifications have required that the sand be clean; the so-called dirty sands have generally been in bad repute. Organic matter has been the principal source of trouble, yet many publications stating that as much as 10 per cent. of loam in sand was not harmful and might even increase the strength of the mortar, are to be found in the engineering journals.

An investigation initiated by Committee C-9 on Concrete and Concrete Aggregates, of the American Society for Testing Materials, showed the desirability of a simple and reliable test which would make it possible to detect sands which contained harmful impurities before they were used in concrete. Commercially, it was also desirable to develop some remedial measure which would make it possible to use sands which in their present condition, on account of impurities, are not satisfactory for concrete.

Disadvantages of Other Methods.

Engineers and chemists have recognized the danger of using sands which contained appreciable amounts of organic matter which may come from surface loam or other sources of contamination, and have used various methods for detecting such impurities. A method which has probably been most used depends upon the loss on ignition. Obviously the loss-on-ignition test drives off, besides the organic matter, the water of crystallization, hydration, etc., and the carbon dioxide (CO_2). In certain "limestone sands" the loss on ignition due to carbon dioxide alone may amount to more than 10 per cent., and yet the sand may be entirely free from organic matter. The determination of the organic matter by combustion has little advantage over the loss-on-ignition method, unless a correction may be made for the carbonates present. Methods which depend upon the moist oxidation of the organic matter have some advantage, but are not entirely satisfactory. None of these methods determines directly the amount of organic matter in the sands. Most of them determine the amount of carbon by first converting it into carbon dioxide. The organic matter is then calculated by multiplying the per cent. of carbon by some factor, the accuracy of which is often questionable.

Limitations of Colorimetric Test.

The colorimetric test for organic impurities in sands represents one phase of the work which has been done at the Structural Materials Research Laboratory, Lewis Institute, Chicago, under the direction of the committee mentioned above. The fact that the sand has passed the colorimetric test does not in itself prove that the sand is suitable for mortar or concrete, since its fineness and other characteristics must also be considered as they affect the strength. The result of the researches, however, indicate that it is a reliable test for organic impurities, which are the most common source of danger in a sand of satisfactory granulometric composition.

It it is intended at this time to give only a description of the methods of making the test so that it may be tried out further in commercial and private laboratories. The experimental data obtained in the course of these studies will furnish the subject matter of a subsequent report.

It will be of assistance to the committee having this investigation in charge, if other experimenters will report the details of their tests and observations to the chairman, Mr. Sanford E. Thompson, 136 Federal street, Boston, Mass., or to the authors.

The colorimetric test may be described briefly as follows:

---

*Structural materials Research Laboratory, Lewis Institute, Chicago. Experimental work carried out in co-operation with Committee C-9 on Concrete and Concrete Aggregates, of the American Society for Testing Materials. Published by permission.

A sample of sand is digested at ordinary temperature in a solution of sodium hydroxide (NaOH). If the sand contains certain organic materials, thought to be largely of a humus nature, the filtered solution resulting from this treatment will be found to be of a color ranging from light yellow up through the reds to that which appears almost black. The depth of color has been found to furnish a measure of the effect of the impurities on the strength of mortars made from such sands. The depth of color may be measured by comparison with proper color standards.

Two methods of procedure have been developed: (1) For field tests; (2) for laboratory tests.

METHODS FOR FIELD TESTS.

Fill a 12-oz. graduated prescription bottle to the 4½-oz. mark with the sand to be tested. Add a 3 per cent. solution of sodium hydroxide until the volume of the sand and solution, after shaking, amounts to 7 oz. Shake thoroughly and let stand over night. Observe the color of the clear supernatant liquid.

In approximate field tests it is not necessary to make comparison with color standards. If the clear supernatant liquid is colorless, or has a light yellow color, the sand may be considered satisfactory so far as organic impurities are concerned. On the other hand, if a dark-colored solution, ranging from dark reds to black, is obtained the sand should be rejected or used only after it has been subjected to the usual mortar strength tests.

Their Uses.

Field tests made in this way are not expected to give quantitative results, but will be found useful in:

(1) Prospecting for sand supplies;

(2) Checking the quality of sand received on the job;

(3) Preliminary exmaination of sands in the laboratory.

An approximate volumetric determination of the silt in sand can be made by measuring or estimating the thickness of the layer of fine material which settles on top of the sand. The per cent. of silt by volume has been found to vary from 1 to 2 times the per cent. by weight.

METHOD FOR LABORATORY TESTS.

To a 200-gram sample of dry sand add 100 c.c. of a 3 per cent. solution of sodium hydroxide (NaOH) and digest at ordinary temperature, with occasional stirring, for 24 hours. Filter this solution through a good grade of filter paper; refilter if necessary. The filtrate *must* be clear. Place 10 c.c. of the *clear* filtrate in a 50 c.c. Nessler cylinder and dilute to 50 c.c. with distilled water. Shake thoroughly and let stand until all foam and bubbles disappear. Determine the color value of this cylinder by comparing it with cylinders containing standard solutions of alkaline sodium tannate. Compare the colors by looking through the full depth of the solution with the cylinders held toward a good natural light.

Standard Tannic Acid Solution.

The preparation of the standard tannic acid solution for comparing the color of the filtrate should be begun at the same time as the treatment of the sand. Add 10 c.c. of a 2 per cent. solution of tannic acid in 10 per cent. alcohol to 90 c.c. of a 3 per cent. solution of sodium hydroxide. The sodium hydroxide combines with the tannic acid to form sodium tannate. Let the solution stand 24 hours at room temperature. Place 1, 2, 3, 4, 5, 6, 7, 8, 9 and 10 c.c., respectively of this solution in 50 c.c. Nessler cylinders and dilute to the mark with distilled water. The amounts of tannic acid in the different cylinders will then be as shown in the following table:

Alkaline Sodium Tannate in each cylinder—cc. ...	1	2	3	4	5	6	7	8	9	10
Tannic acid in each cylinder—milligrams	2	4	6	8	10	12	14	16	18	20
Color value in parts of tannic acid per million of sand by weight	100	200	300	400	500	600	700	800	900	1000

It is desirable to have good sunlight for comparing the colors; if sunlight is not available, the amount of tannic acid in each of the cylinders containing the standard solutions may be decreased by one-half and the other values in the table modified accordingly.

In case the solution obtained by digesting the sand with the sodium hydroxide is very dark, use less than 10 c.c. for the comparison and make the necessary modifications in the calculation of the color values. With very light-colored solutions use more than 10 c.c. of the filtrate for the comparisons. The depth of color of the solution decreases on standing, and for that reason the solution should be made up fresh for each day's work.

Calculating Color Values.

Method of Calculation. An example will make clear the method of calculating the color value of a sand. Suppose that 10 c.c. of clear filtrate obtained by digesting the sand with 100 c.c. of a 3 per cent. solution of sodium hydroxide when diluted to 50 c.c. corresponds in color to the Nessler cylinder containing 12 milligrams of tannic acid, or 6 c.c. of the alkaline tannate solution. The sand will then have a color value of 600. The 10 c.c. of the filtrate placed in the Nessler cylinder is 1/10 of the 100 c.c. of 3 per cent. sodium hydroxide solution which was added to the sand, and the sample of sand (200 grams) is 1/5 of a kilogram; therefore, the milligrams of the tannic acid per kilogram of the sand, by weight, are $12 \times 10 \times 5 = 600$; or the tannic acid equivalent when expressed in parts per million of the sand, by weight, is 600.

Basis of Colorimetric Test.

The colorimetric test has been applied to sands from about 40 widely distributed deposits in 20 different states. The research to date has brought out the following:

1. Examinations of deposits of defective sands show

that surface loam is the principal source of contamination.

2. All natural sands which have been found to be defective on account of the presence of organic impurities have responded to the colorimetric test with sodium hydroxide, and all sands which have given high color values have shown low values in mortar tests.

3. Sands which were similarly graded by screening out and recombing the different sizes to a definite sieve analysis showed a fairly definite relation between the compressive strengths of 1-3 mortars at 7 and 28 days and the color values of the sands.

4. The mortar-making quality of sands known to contain organic impurities has been much improved by removing the organic matter, either by repeatedly digesting them with sodium hydroxide and then washing free from alkali, or by driving off the organic impurities by ignition.

5. When the sodium hydroxide extracts from sands which mortar tests had shown to be defective were purified and applied as coatings on high-grade sand, that sand was made "defective" or gave much reduced mortar strength.

6. It is impracticable to give exact values for the relation between the color value of a sand and the strength of mortars made from the same sand. However, the tests made thus far show this relation to be about as follows:

Color Values of Sand	Reduction in Compressive Strength of 1/3 Mortar Per Cent
250	10-20
500	15-30
1000	20-40
2000	25-50
3000	30-60

The reduction in strength is based on compression tests at ages of 7 days, 28 days, and 3 months of 1/3 mortars made from the same sand before and after coating with different per cents. or organic impurities which had been extracted from defective sands and purified. Tests on mortars made from defective sands as received and after removal of the organic impurities, either by repeated extractions with sodium hydroxide or by ignition, showed that in some cases the reduction in strength for a given color value was even greater than the higher values given above. Frequently the test pieces completely disintegrated in the storage water. The higher reductions in strength for a given color value for a natural sand as compared with the same color value for an artificially coated sand is probably due to the artificial coating being more easily removed by sodium hydroxide.

Sufficient data are not available to indicate whether or not the effect of a given quantity of organic impurities varies with the grading of the sand. The reduction in strength seems to decrease slightly with the age of the test pieces.

The apparatus required for making the colorimetric test of sands will vary according to the nature of the investigation.

The time actually required for a single determination by the laboratory method is about one-half hour. If tests on as many as five samples can be made at once the total time consumed need not exceed one hour. The time required from the beginning to the end of the test is about 24 hours.

Experience Not Necessary.

Inexperienced operators without technical training or previous experience in work of this character have secured satisfactory results at their first trials.

The strength test of mortar is used as the criterion of the effect of impurities in sand. In making strength tests of sand mortars and interpreting the results of such tests the following points require particular attention:

(a) Sampling of sand,
(b) Grading of sand,
(c) Quantity of water used in mixing,
(d) Methods of mixing, molding and testing,
(e) Form and size of test piece.

(a) Great care is necessary to insure that the sample tested is representative of the larger lot of sand. Good judgment and considerable experience are necessary to secure representative samples from an undeveloped deposit. Some form of sampler should be used in the laboratory in selecting a test sample from a larger lot.

(b) The size and grading has an important influence on the concrete and mortar-making qualities of sands. A sand graded from coarse to fine, with the coarse particles up to about one-quarter inch in diameter, is desirable for use in concrete. Fine sands when mixed to the same plasticity give mortar strengths much below those of coarse, well-graded sands. The influence of the grading of sand on the strength of the mortar must not be confused with the effect of impurities.

(c) The quantity of water used in mortar tests has just as important an influence on the strength as the amount of cement. The quantity of water required for normal consistency of mortar made from a given cement is a function of the grading of the sand.

(d) The methods used in mixing, molding the test pieces, storing and testing the specimens, etc., used in standard tests of cement should be followed in making strength tests of sand mortars.

(e) Compression tests of mortar are believed to be more significant than tension tests. A 2 by 4 inch cylinder has been found to give satisfactory results as a compression test piece. This is the form of test piece recommended by the American Society for Testing Materials in their proposed tentative specification for compression tests of cement.

The funds for this investigation were furnished by Committee C-9 on Concrete and Concrete Aggregates of the American Society for Testing Materials, Sanford E. Thompson, Boston, Mass., Chairman; F. W. Kelley, Albany, N. Y., Chairman of Sub-Committee V. on Impurities Affecting Fine Aggregates for Concrete.

CHEMICAL CONTROL IN THE LEATHER INDUSTRY

By David Quick Hammond.*

Wide Fields for Personal Research Leading to Improvements in Reactions Now Carried On in Tanning Processes, Are Herewith Pointed Out by Mr. Hammond in His Interesting Discussion of Past and Present Aspects of This Branch of Industrial Chemistry.

IN order that the relationship of chemistry to the leather industry may be made clear, it is necessary that a brief discussion of the processes of leather manufacture first be given. At best it is possible to deal only in generalities, for each tanner has his own individual ideas and formulae which are especially adapted to the class of hides with which he deals and the use to which the finished product is to be put. Perhaps it will not be altogether out of place to speak likewise of the cordial(?) relations which have, in the past, sometimes existed between the tanner and the chemist.

The average tanner has often been, heretofore, the most incredulous of business men, due no doubt to the very secrecy with which he has attempted to keep his methods from his competitors. Tanning is a purely chemical process, despite the fact that this industry has prospered for years without any attempt being made to "chemicalize" it. Leather has long been manufactured by rule-of-thumb methods, the tanner knowing that such and such a process would bring about such and such a result without fully understanding just *why* it did. Any new methods were always discovered by trial and elimination, not by theoretical knowledge.

In a chemical process such as the tanning of leather it is impossible for any process to be practical unless it is first possible from a theoretical chemical standpoint, although a process theoretically possible is not always practical. The tanner, because of his innate skepticism, formerly refused to believe in the value of an untried process just because it happened to be evolved by a reputable chemist. He demanded an ocular demonstration that the process could be accomplished successfully in a tannery as well as in the laboratory. And because such a demonstration necessitated the risking of his own capital on what, to him, probably looked like the roseate hope of an impractical theorist, the matter usually ended there. It has been only very recently that the chemist has become recognized as essential to the tanning industry.

Early Lack of Mutual Understanding.

Sixty-three years ago a German chemist published an article setting forth a new method for the tanning of leather, namely, by the use of potassium dichromate. At this time leather was being tanned only with barks and by methods not differing greatly from those employed by our aboriginal ancestors. It is therefore easy to see what an entirely new departure this was, but for all that, the article was given no credence, due in part, perhaps, to the fact that it was couched in purely theoretical chemical terms, and likewise because the chemist admitted freely that the process had not been tried in a practical way. This was followed shortly by another article written by an English chemist describing a process for a two-bath chrome tannage which was almost identical with the chrome processes now in use. Perhaps the article went unnoticed by the tanners of the day; more probably it was lacking in cold facts when considered from a practical standpoint, and was, therefore, looked upon as a dream. Suffice it to say that it was not until nearly forty years later that the method was tried by some progressive tanner, or perhaps rediscovered, and found to be entirely successful.

It is largely due to a few of the younger and more progressive tanners, and a few chemists who realized that what can be done in a test tube cannot always be done in a factory, that the chemist and the tanner are at last in full accord. These chemists worked out the tanners' problems at the factory in a practical manner and developed systems for the chemical control of the processes. Chemistry, however, is not yet so prevalent in our tanneries as in our steel plants, our rolling mills and our munition factories, because the application of chemical control to this industry is still in its infancy. Chemists have expended their energies in bringing about definite results, but for all that, the analysis of vegetable tanning materials and oils is still made merely on a comparative basis, and possible only by the efforts of the American Leather Chemists' Association in standardizing the methods to be used.

Tanning Methods in General Use.

Let us turn, then, to the actual methods employed. Tanning is a process which changes a perishable, putrefying hide or skin into a stable, non-putrefying article known as leather. The hide, which is in a green, salted or dried condition, as the case may be (not taking into consideration the pickled skins from Australia, etc.), must first be brought back as nearly as possible to the condition it was in directly after being removed from the animal. This is accomplished by soaking it in water for from three to five days in the case of green hides and longer in the case of the dry. The soaking should also remove all dirt, filth and salt, because their presence would interfere with a uniform action of the lime, which is applied later. Unless completely removed, the salt leaves a so-called "salt-stain" after coming in contact with the lime, and this stain could not thereafter be removed throughout the entire process.

---

*Leather Chemist, 27 Putnam St., Tunkhannock, Pa.

The object of "liming," or placing the hides in vats filled with water and suspended $Ca(OH)_2$, is to eat away the outer skin surrounding the hair sacs, so that the hair may easily be removed by scraping, and to swell or "plump" the fibers of the hide so that they will be open to receive the tanning material. The liming is accomplished in four or five days, 8 pounds of lime being used for every 100 pounds of hides. After the hair and flesh have been removed, the lime itself, if what is known as the "acid" process, where the tannin enters the hide in the presence of a strongly acid solution, is being employed, must also be removed, for strong acid on a hide containing lime will cause brittleness.

Action of the Bate.

The lime is removed by "bateing" with hen or dog manure and wheat bran, which carries, or produces, a species of bacteria which destroy the lime. The power of these bacteria ceases automatically when all the lime has been removed, but immediately another species of bacteria, which are inactive in the presence of lime, now become active in its absence and begin to destroy the hide substance. At this point the bate must be quickly removed from the hides. There is a patent bate known as "Oropon," which is used very successfully, as it contains only the bacteria which destroy the lime, and therefore can be used without danger of any loss of hide substance. Hides which are to be tanned with a tanning solution which is only mildly acid, however, need not be bated at all, if as much of the lime as possible is first removed by washing and drumming with water.

Bateing depletes the hides, and they must again be plumped in order that the fibers may be open to receive the tanning material. This is accomplished by pickling the hides in a solution of one part by weight of concentrated 66° H_2SO_4 to 8 parts by weight of NaCl.

Reactions of Two Classes of Tannage.

The hides are now ready for the tanning material, which may be divided into two classes, vegetable and mineral tannage. Tannin, which belongs to the former class, is to be found in numerous vegetable growths such as the barks of oak, hemlock and chestnut trees, and in various plants, nuts, pods, etc., of tropical and semi-tropical varieties. Perhaps tannin is to be found most abundantly in the roots of the palmetto tree, from which source it is obtained in larger and larger percentages as we approach the equator. The tannin is leached or percolated out with water in the presence of heat and placed in contact with the hides in varying strength, according to the process used. Combination of the tannic acid with the constituents of the corium is effected, and the hide is thereby rendered tougher, less permeable and nonputrescible.

Mineral tannage consists chiefly of chrome tanning, which is accomplished by milling the hides with the solution of a mixture of potassium dicromate, HCl and NaCl, and later with sodium thiosulphate, which acts as a reducing agent and effects the precipitation of Cr_2O_3 between the fibers of the hide. This completes the tanning process, and it remains only to "finish" the leather in any manner desired.

I have given this very general description, not with the idea of presenting a detailed exposition of the actual manufacture of leather, but in order to be able to point out clearly just where the possibilities for personal research lie in the leather industry.

Wide Field for Original Research.

Quite naturally, we turn first to chemical control. The "soaks," where the hides are soaked in water to be cleansed before entering the "limes," use running water. What kind of water brings about the desired effect most efficiently? Instantly we encounter a wide dissociation of opinion, for one tanner will say hard water; another, medium, while still another—if you can make him talk—will tell you that he has been most successful with soft water.

Next we may consider the action of the lime on the hide substance, which, of course, is composed chiefly of gelatine. How does it act? We know that it acts on the hide with the formation of ammonia; that the vigor of the reaction increases as the temperature rises, and that the formation of additional ammonia also hastens the reaction. The crude lime to be employed should be analyzed for the presence of available CaO, it being the lime in solution, of course, which acts on the hide. Although lime is less soluble in hot water than it is in cold, it is perpectly natural that the increase in the speed of the reaction attendant upon a rise in temperature should more than overbalance the loss in strength of the saturated solution of lime. The contents of the lime vats should be analyzed for the presence of ammonia, which is a check on the loss of hide substance.

In connection with the hair, which is recovered and sold as a by-product, let me say that the chemist who discovers a cheap practical method for bleaching dark hair pure white, will make a fortune, for the white hair sells for seventeen cents per pound more than the dark hair. The "fleshings," from which the oil is extracted, are sold as "glue-stock," from which gelatine is made. There is ample opportunity for research here. In the matter of bate, the inventor of "Oropon" has a pretty clear field at present, but improvements will be made, no doubt, in this field also.

Both Methods Need Acurate Control.

The control of the chrome tanning process is plain analytical chemistry, although a seemingly simple analysis often produces great difficulty, for chromium is a highly refractory metal to analyze when in the presence of other minerals found in tanning liquors. In a majority of cases I have found it best to employ the volumetric method, using potassium iodide, starch paste and sodium thiosulphate, after first "popping" with sodium peroxide and neutralizing with hydrochloric acid. It is sometimes necessary to precipitate the chromium as the hydroxide with ammonia, after destroying the organic matter present with aqua regia, but often it is impossible to feel in any way certain as to the accuracy of the result because of the organic matter. Some very useful research would not be out of place with regard to this analysis, as the necessity of accurate chemical control at this point in the tanning process needs no emphasis on my part.

It is, however, the vegetable tannins which offer the widest field for research. New tanning materials are being put upon the market constantly. The chemistry of the vegetable tannin is but little understood, for its analysis is based on the amount taken out by treatment with hide powder. The analysis referred to is a comparative rather than an accurate one, much as is the case with a coal analysis, and the final result is merely a more or less accurate comparison. I believe that a far more accurate analysis is possible, and that such a one will eventually be developed. The absolute necessity of chemical control of these tanning liquors is self-evident from an efficiency standpoint alone. There are control processes now in use, but they are far from having attained an ideal state, and I believe every tannery chemist will agree that there is great room for improvement.

Oil Analysis Not True Guide to Tanner.

Sulphonated cod oil, menhaden and mineral oils are used extensively in the tanning industry. The tanner demands various chemical specifications for the oils which he uses, but not, mark you, because the *combination* of properties written on the analysis card indicates to him the suitability of a given oil to his particular needs, but merely because he has at some time successfully used an oil having a certain property, *among the other properties listed*. Thenceforth he has associated the presence of this single property in an oil with his success, and would in future reject another oil having a *combination* of properties far better suited, perhaps, to his needs in favor of any oil whose analysis card indicated its presence. The oil analysis in general use for tanning oils is, therefore, something of a farce so far as acting as a guide in the tanner's selection of an oil is concerned; it means little to the tanner himself. There is great need for an oil analysis which will give a ratio, or some definite grading of characteristics which would show the true values of oils in their application to various kinds of leather.

Some of the larger leather concerns maintain extensive laboratories, but naturally they are not publishing the results of their costly researches. In the encouragement of her industrial chemists, America is only beginning now to do what Germany has been doing for years.

Awakened to the fact that many of them were confronting a serious predicament as a result of the war, American manufacturers bestirred themselves, looked the situation over, and then demanded petulantly why American chemists could not produce for them the dyestuffs, intermediates and a host of other materials which were obtained formerly from Germany. And the answer is: They can—if they receive in future the moral and financial backing which the German chemists have always received.

Wanted—More Faith in the Chemist.

It is a historical fact that the Badisch Dye Company, in Germany, spent *ten years* and *twenty millions of dollars* in practical research work before a single pound of dye was placed on the market. Would any group of American business men have sufficient faith in the American chemist to risk so much capital without being certain of the returns? Or assuming that they *were* absolutely certain of adequate returns, would American business men be content to wait so long for those returns? Most assuredly not, particularly in the past, and for this reason the American industrial chemist has thus far been outstripped by his German brother. For the future no one can answer, but there is every reason to hope for better co-operation, now that the further possibilities have been brought squarely before our financiers.

The Chemist, Too, Can Help.

And the industrial chemists themselves have not been wholly without blame for the existing state of affairs. They must learn to school themselves still more to the idea that a new process successfully carried out in the laboratory is only half completed until they have also devised a method to demonstrate conclusively its adaptability to actual manufacturing conditions. They must learn to become, if not actually business men themselves, at least able to translate the results of their activities into business terms. American chemists are progressing rapidly along this line, and there is no doubt but that the approaching financial backing of some of our larger corporations will soon bring the American chemist second to none.

SYNTHETIC INDIGO IN U. S.

A new departure marking an important step in American coal tar color manufacture was achieved by the Dow Chemical Company, of Midland, Mich., when it began recently the production of synthetic indigo. The daily output of the plant is said to be about 5,000 pounds of 20 per cent. paste. Since the outbreak of the war the sole synthetic indigo to reach this country has been from a single plant in Basle, Switzerland.

New Pharmaceutical Company.

Under the laws of New Jersey the Glyzine Company, pharmaceuticals, of 870 Broad street, Newark, has been incorporated with a capital stock of $25,000.

CRYSTALLIZATION OF CREAM OF TARTAR IN THE FRUIT OF GRAPES

By William B. Alwood.[*]

Experiments Carried on at U. S. Enological Laboratory Reveal the Natural Deposition of Patassium Bitartrate During the Ripening Process.

During the chemical examinations made of the ripening of grapes in the Enological Laboratory, Charlottesville, Va., the writer was led to conclude that the acid salt bitartrate of potassium was deposited from the juice in quantity sufficient to sensibly affect the analytical results. This led to the preparation of samples by the complete exhaustion of the soluble constituents of the berries, with results which supported the above conclusion.

The question of the character and location of the crystals of cream of tartar in the berry presented itself as a matter of interest and possibly of practical importance. The literature available did not furnish specific information on this point. Babo and Mach, in their exhaustive treatise, give but one brief reference to the occurence of this salt in crystals in the fruit.

As soon as the fruit was well colored at Charlottesville in 1912 a series of microscopic examinations was undertaken to determine whether crystals of bitartrate of potassium occurred in the fruit. Portions of Concord grapes were prepared and examined daily until the fruit was ripe. Minute crystals varying much in shape and size were found in great abundance in the soft cells lying just beneath the skin of the fruit. Crystals were not present at any time in the pulp or compact portion of the flesh in which the seeds are contained. Like examinations of Concord and Catawba were carried on at Sandusky, Ohio, in September and October, 1912, and crystals of the same general type were found.

The fact that many of the crystals found in the berries did not conform in type to crystals of the bitartrate prepared from pure cream of tartar made it doubtful as to whether potassium bitartrate was deposited or not. Therefore, the fruit was separated into portions for the purpose of a chemical examination covering this point. The tough pulp containing the seeds of 1,500 grams of ripe berries was separated from the hulls and soft peripheral layer of cells which adhere to the hulls. This layer contains the coloring matter. The hulls and pulp were then carefully pressed by hand and the juice of each recovered and held separately. This gave three portions: (1) The pressed hulls, (2) the juice recovered from the hulls, and (3) the juice recovered from the pulp.

In preparing the sample, all the juice possible was recovered from the sample of hulls and pulp; that is, they were entirely exhausted so far as crushing and pressing could accomplish this result. The pressed hulls were then carefully macerated in distilled water until the soluble organic matter was exhausted. These portions showed on analysis the results given in Table I.

TABLE I.

Analyses of Concord grapes in 1912, giving the percentage by weight of acids and acid salts.

Portion analyzed.	Total acid.	Total tartaric acid.	Free tartaric acid.	Cream of tartar.
Hulls exhausted with water.	0.429	*0.589	0.08	0.56
Juice pressed from hulls.....	.141	.054	.00	.07
Juice pressed from pulp.....	1.065	.724	.20	.59

*The results show for the samples of "hulls" a greater content of tartaric acid than the total titratable acid of the samples. This is always the case in grape samples where the "acids other than tartaric" fall below a certain proportion.

The results show that the juice pressed from the hulls is very low in acid and acid salts, and that, while the organic matter remaining in the hulls after pressure is less than half as acid as the pulp, it is rich in tartaric acid and cream of tartar, in these regards nearly equaling the percentage found in the juicy pulp. The actual weight of the pressed hulls was 304 grams, or one-fifth of the original sample of fruit. From the results given, it would appear that the hulls when pressed dry still retained the crystals observed with the microscope, and actual observation has demonstrated this fact. The results for tartaric acid and cream of tartar settle the point as to the composition of these crystals.

In 1913 the microscopic examinations were begun much earlier, and four varieties of grapes were included—Delaware, Concord, Niagara and Norton. The presence of crystals of bitartrate of potassium could be observed before the berries were all colored, and the analyses of partly ripe fruit confirm the results of 1912. These samples were separated into two portions only, the hulls and the pulp, as noted above; then each sample was completely exhausted of soluble organic matter by repeated macerations and heating in distilled water. Table II gives the results for one set of samples from each of two varieties.

TABLE II.

Analyses of grapes in 1913, giving percentage by weight of acids and acid salts.

Portion analyzed.	Total acid.	Total tartaric acid.	Free tartaric acid.	Cream of tartar.
Concord.				
Hulls	0.95	*1.11	.00	1.33
Pulp	1.43	.79	.04	.82
Niagara.				
Hulls	0.67	*0.93	.00	1.18
Pulp	.96	.83	.18	.57

*The results show for the samples of "hulls" a greater content of tartaric acid than the total titratable acid of the samples. This is always the case in grape samples where the "acids other than tartaric" fall below a certain proportion.

There are crystals other than bitartrate present in the fruit, but this paper is intended only to record an observation which may have peculiar interest. Further details of the investigation will appear later.

IMPROVEMENTS IN WASTE DISPOSAL PLANTS

By Gustave R. Tuska, M. S. C. E.*

GUSTAVE R. TUSKA.
Copyright, Underwood & Underwood, New York.

Although Costing Considerably More for Fuel and Solvent Than a Plant Operated on the Digester System, the Process Here Dealt With Obviates All Odors and Losses Due to Carbonization, and Greatly Increases the Recovery of Ammonia and Potash.

THE growing public interest in the general recovery of by-products heretofore wasted, and in the effort to avoid the destruction of any useful materials, has been especially evident in the discussion of the disposal of municipal waste. This interest has naturally been extended not only to the processes and methods used in the disposal of such wastes, but also to the matter of the ownership of such plants, and whether they are to be municipally or privately operated.

From the standpoint of the public, however, every consideration in the design and construction of such plants should be subordinated to the question of their being built and operated according to the most sanitary methods. The first cost of the plant and its cost of operation should only be considered after the question of sanitation.

The municipal wastes above referred to consist of ashes, rubbish and garbage.

In the matter of the handling of the ashes and rubbish there have been no marked improvements during the last few years. "Filling in" with the ashes and incineration of the rubbish still continue to be the best methods when these materials are handled separately. When they are disposed of in combination with the garbage, high temperature destructors are used. Except in the matter of some of the details of the design and operation of these destructors there have been no important improvements made during the last few years.

Two Methods of Garbage Disposal.

As to the disposal of the garbage of large municipalities, two methods in the main are used. First, disposal in the high temperature destructor furnaces referred to above, and second, disposal by reduction processes, in the course of which there are recovered from the garbage grease and low grade ammoniates, both of which materials are of considerable commercial value. It is in the methods of reduction for the handling of garbage that the greatest improvements have been made in the last few years. Formerly, where successful reduction processes were used, they were only of two types—one, where the garbage was mechanically dried in hot-air furnaces and the grease then extracted by means of a chemical solvent and the material then redried so as to produce a commercial product, and second, where the garbage was digested, pressed and mechanically dried, the grease being extracted partly by pressing and partly by degreasing with chemical solvents.

These processes have been in use in all large American cities where reduction of garbage has been followed and in almost every case strong objections have been raised to the operation of such plants on account of the nuisances created. The main objections to these plants have arisen from the gases produced in the destruction of the garbage and from the gases discharged in the drying processes used in these plants.

A New Process.

To obviate these objections a new reduction process has lately been evolved. The operation of this process is as follows:

The raw garbage is placed in a closed tank which is sealed air tight. This tank or reducer is constructed with jacketed walls and jacketed bottom. Into these jackets the steam which is used in the reduction of the garbage is delivered, these jackets being so designed that it is impossible under proper operation for the steam to enter the tank or come in contact with the garbage. In the interior of this tank there is an agitating device operated by power from the exterior. When the proper charge of garbage has been placed in the reducer and the covers placed thereon the tanks are sealed and the solvent is pumped into the reducer and steam admitted to the jacketed walls. The heat from the steam which is transmitted to the garbage through the walls of the reducer causes the evaporation of the solvent and the water in the garbage.

Garbage is usually composed of over seventy-five per cent. by weight of water. The steam heat vaporizes the solvent and the water from the garbage, and these mixed vapors are drawn off from the reducer to the condenser. The economy in this method of evaporation rests on the fact that water is vaporized at a lower temperature when evaporated with a solvent having a low boiling point than when evaporated without such solvent.

Solvent Retained for Further Use.

The mixed vapors of the solvent and the water while in the condenser are there condensed to a liquid state and the water and solvent together are conveyed to a closed tank. Owing to the solvent being of lighter specific gravity than the water, the solvent and the water are separated by gravity, the solvent rising to the top, from where it is drawn back to the storage tanks, from which it is pumped back to the reducers and used over and over again. The condensed water, which has been largely diluted owing to the jet condensers used, is discharged into sewers or waterways.

---

*Lecturer on Municipal Waste Disposal at Columbia University. Consulting Engineer, 68 William St., New York City.

Paper read at Section D, Engineering, of the American Association for the Advancement of Science, December, 1916.

When the garbage has been thoroughly dried by this method the solvent is pumped into the reducer and dissolves the grease. The solvent with the grease is drawn off into a closed tank or evaporator, where it is heated by steam pipes, the steam being kept separated from the grease. The solvent therein is vaporized and carried to a condenser, where it is again liquified and carried to the storage tanks to be used again.

After the grease has been extracted from the garbage in the reducer the latter is further dried by means of the steam in the jacketed walls and is now in the form of de-greased garbage tankage, which is used for fertilizer purposes after being ground and screened.

It will be seen from the above description of the process that if there are any leakages or vents in any of the tanks or piping where the solvent is handled more or less of the solvent is lost, and thereby a substantial additional expense is imposed upon the operation of the system. It is evident therefore that it is to the financial interest of the owner of the plant to see that the same is properly operated. Furthermore, under this system the garbage is at no time brought in contact with the atmosphere, from the time of its original entrance into the reducer until after over twelve hours of cooking; it is finally discharged therefrom as finished products, dried, sterile and practically odorless. These finished products are grease and the tankage above referred to.

Gases Kept in Solution.

It will be seen from the above description that the process is one of straight dehydration, and from the time that the material is at the boiling point no further chemical action in the material takes place. No process of "digestion" occurs, and therefore the odors and gases incidental to such a process are not created. Only the volume of gas contained in the raw material is driven out, and only the essential oils of an extremely volatile nature are carried over in the current of steam and solvent vapor evolved. That little or no conversion takes place in the operation is shown by the fact that in the dehydrated material obtained at the end of the operation there exists practically the same amount of unconverted starchy bodies as existed in the garbage at the time of its entrance into the reducer.

The water condensed contains all the gases evolved and has when fresh a slight odor of the mixed essential oils. Some traces of alcohol are detected in the effluent and a very small quantity of fixed oils is carried over. Any ammonia evolved, if it has escaped the acid in the garbage, is neutralized by acid carried over in the vapor. Whatever albuminoid ammonia exists in the effluent is carried over by mechanical entrainment as dust particles during the steaming out of the solvent.

The effluent from this process consists of almost pure water, this water being the condensed moisture drawn from the reducer while the garbage is being treated and from which the solvent has been extracted as completely as possible. The effluent is cold and gives forth no steam or vapor and is practically odorless, and as a result can have no undesirable effects when run into a large body of water.

Slight Odors Strictly Localized.

The only other possible source of odor during the entire reducing operation would be from the odor contained in the air and gases mechanically included in the green garbage prior to its entrance into the reducer. These gases, plus the air in the reducer itself at the time of filling, are driven out by the first rush of solvent vapor. The entire volume of such gases is so small that no objectionable condition can be created by their discharge.

As regards any odor from the tankage when this material is taken out from the reducer, it is in a dry condition and quite warm, and when it is first exposed to the atmosphere there is momentarily a slight odor of dried material, best described as a smell of stale gingerbread, due to the essential oils rising from the material when hot. No gases are generated, and this odor lasts only during the period of emptying of the reducer and is not offensive or perceptible outside the building.

It will be seen that in the operation of garbage treatment by this process there is no period of gas generation and no large volumes of decomposition and combustion gases given off as in digestion and drying. There is, therefore, no necessity for condensing, washing or trapping odors or gases.

A further improvement has also been made in the solvent employed in the de-greasing process. Heretofore gasoline has been used for this purpose, but it has been proved that a more economical operation and elimination of the danger of explosions is obtained by the use of a kerosene distillate, obtained by the treatment of ordinary kerosene in a vacuum still.

Increased Expense Justified.

The cost of a plant operating on the above system is from twenty-five to fifty per cent more expensive than one on the digester system. The cost of operation per ton of garbage by this system is also considerably higher than by the digester system, the labor cost being about the same, but the cost for fuel and solvent being considerably greater.

As against this increased cost, we have superior sanitary advantages and a considerably greater value of recovered products. By the use of this process a larger grease recovery is obtained, also a more valuable tankage. Where the digester system is employed the potash contained in the vegetable fiber, being soluble, is lost in the discharged water. With this process it remains in the tankage amounting to over 1 per cent by weight in the dried product.

Furthermore, with the digester system the largest portion of the water contained in the garbage is removed by pressing. This water, discharged from the presses, carries 8 per cent of solids by weight and is the most valuable for fertilizer purposes, as it contains all the ammonia and potash which is water soluble. All such material is recovered by this process. In addition, with the digester system where direct heat dryers are used there results a large loss of solids (tankage, grease and fibrous material), averaging about 20 per cent of the total weight of tankage fed into the dryer. This loss is due to carbonization of the materials named and results in various odors and gases. This loss with the resultant gases is avoided by this process.

CHEMISTRY AND ENGINEERING.

By Dr. Charles Carpenter.*

A Timely Message to the Industrial Chemist.

Lack of Mutual Respect for Each Other's Professions Between a Chemist and an Engineer Co-operating In the Erection of a Plant Frequently Spells Inefficiency and Waste, Declares the Writer—For the Benefit of Chemists He Here Describes the Training and Methods of the Engineer and Explains a Remedy Which Was Tried Successfully.

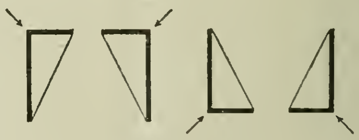
I PROPOSE to initiate a talk about chemists and engineers and their relationship to the great problems of bringing up to date our national chemical industries. The charter of the Institution of Civil Engineers defines the profession of the engineer as being the art of directing the great sources of power in Nature for the use and convenience of man. We might, in similar language, define the aim of the chemist as being to wrest from Nature some of her most hidden secrets for the same purpose. (I attach no importance to the definition of a chemist which describes him as an organic body more liable than any other of similar nature to spontaneous explosions.)

As I am talking to chemists, and not engineers, it will be best to begin at the beginning, even at the risk of seeming elementary. The popular conception of the engineer is that he is an empiric who has been trained on cotton waste and engine oil. This is, of course, a fallacy. He has just as scientific a foundation for his work as has the organic chemist, and, like him, has a *ring structure* from which spring his great creations. His ring, however, is centuries older and is basic in its simplicity. The diagram (Fig. 1) shows several such rings. Their form is a triangle with rigid sides and a flexible base. If force is applied to the apex, the ring is stable and resists distortion under the stress; in other words, it does the work for which it is designed. If force is applied to either of the two angles, it is seen to be unstable, and collapses.

Evolution of the Compound Ring.

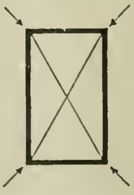
Two such rings may be joined together with a common base, and the two rings so coupled become a structure which has similar attributes to its components. If force be applied to either or both apexes, this double ring is stable; if to the opposite angles, it is unstable. But if the complete rings are combined to form a compound ring (Fig. 2) the structure becomes a stable one in all directions. The ring formation thus described is the basis of all construction and building in metals, from the framework of the Forth Bridge to that of a Zeppelin.

Let us now consider how the engineer sets out to achieve the task with which he has been intrusted. One of the necessary qualifications of an engineer is the possession of an imaginative faculty; he must see in his mind's eye the general outline of his finished production before it is designed in detail or its creation is begun. What will be his procedure if his work be the construction of, say, the former structure of the two examples just given? Drawings or maps would be useless to him without knowledge of the surrounding landscape itself. He goes then to seek inspiration on



Simple Ring Structures

FIG. I.



Compound Ring Structure.

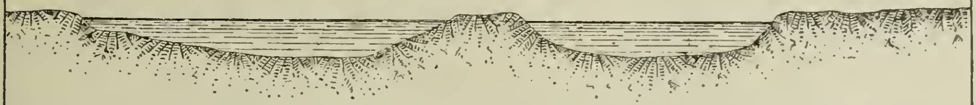

FIG. 3.

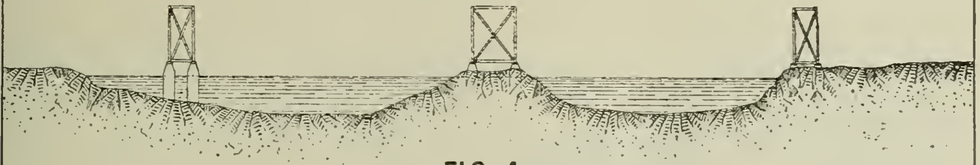

FIG. 4.

the spot just as a painter would to visualize and make studies for this picture. He watches the long slope of land stretching down to the river's edge from Fife on the one shore and from Linlithgow on the other, and realizes that what he builds must join those widely separated crests. He sees before him between midstream and the right bank the islet of Inchgarvie lifting its rocky head above the waters of the Forth.

Practical Application of the Ring.

Then begin his musings, and gradually the mists clear and the mental creation of his work begins. He dreams of setting up on the edge of the river a compound ring structure, placing another on Inchgarvie, and then as the expanse of stream beyond makes the width of span impossible, the idea comes to him of building for himself another islet in steel and artificial stone corresponding to Inchgarvie and reaching up from the river bed. At these three points he erects his massive compound rings, and from both sides of them he then proceeds to build out other rings, each balancing the other and growing smaller and smaller as they strech to meet each other across the waters below. He joins the gaps with smaller bridges until he makes the whole structure a continuous one from shore to shore. Observe the language of the engineer, Titan that he is. He has faith in himself, in his ability to master Nature, and he *throws* a bridge across what she made as a widely-parted chasm. The diagrams show the progress of the work. Fig. 3 represents a profile of the spot looking down stream in which Inchgarvie is prominent. The next diagram (Fig. 4) shows the artificial island he plants solidly upon the river's rocky bed on which his compound "rings" stand on feet or bases, and soaring upward for a height of 350 feet. These "rings" are drawn more in detail in Fig. 5, which clearly shows the building up of the structure from simple triangles. The sixth diagram shows the completion of the arms or cantilevers jutting widely out from the big ring, like the arms of some great monster seeking his mate. The seventh diagram gives a more general view of them before joining up, and the eighth figure shows the completed structure itself, more than a mile long and with a clear headway from high water mark of 150 feet, under which our great dreadnoughts can pass at will.

Former Status of the Engineer.

I want now to invite your consideration of the engineer from another point of view, and which bears a certain resemblance to the immediate necessities of our own industries. The picture on the screen (this was shown at the meeting) is from a drawing made between a half and three-quarters of a century ago. The vessel in the background is a first-class battleship, oak-built and wind propelled. The steamship is the Admiral's tender, and bears a name still honored in the Service. It is a picture of the beginning of the mighty Navy which now protects our shores, and which includes battle cruisers of such an enormous size that some of them consume fuel at the rate of an equivalent of over one thousand tons of coal per day. Imagine the mechanism of the appliances capable of first producing energy on such a scale down in the bottom of the ship's hold and then of utilizing it within her walls! No one could have any doubts as to the important part

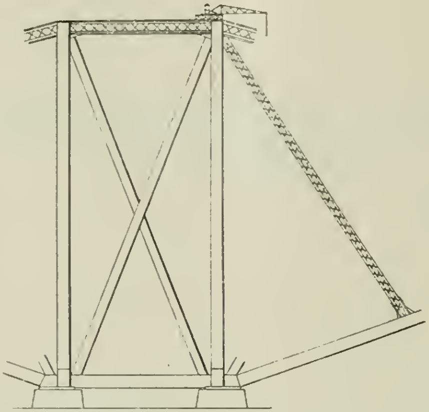

FIG. 5.

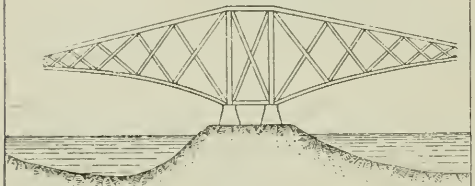

FIG. 6.

which must be played by the engineer in such an organization.

Now, from the earliest days of the application of steam to the Royal Navy until quite modern times its engineers were looked upon in the same, more or less, contemptuous fashion as they are, not infrequently, by chemists today. For many a day they messed apart from the ship's officers, whose butt for ridicule they often were. In recent years, however, one man great above his fellows set himself to remedy this state of things, which threatened seriously to menace the efficiency of the Navy and the safety of our Empire. That man is the present Lord Fisher, and I now want to tell you something of the work which he set himself to accomplish. With, I think, the thoroughness born of the Service to which from boyhood he was attached, he realized the importance of beginning life early, and instead of taking youths, who are more or less spoilt by the kind of training given them at the public schools, the entering age for a Naval cadet was made 13 years or a little more. At that age he is expected to satisfy his examiners in English, History, Geography, Arithmetic, Geometry, French or German, with some knowledge of Latin.

Engineers Selected Early in Life.

From that time his training begins in Physics, Chemistry, Applied Mechanics, Applied Electricity, and, above all, in Engineering and workshop practice. Until he is 17 years of age and goes to sea, that is the training of every officer in His Majesty's Navy. Whether he may be destined for a battleship commander, an engineer commander, or head of dockyard, the value of engineering in the making of a man is recognized from the commencement. There is, of course, a preliminary sorting out which is of great interest and importance.

Engineering in Chemical Industry.

Now it seems to me that the condition of affairs in Chemical Industry is very much akin to what has happened in the Navy, viz., that specialized engineering is becoming more and more necessary to it.

I had hoped to have been able to give you on the screen one or two pictures of a modern German-built chemical works, erected on British soil under the regulations of our Patent Laws, but forfeited to the Nation as a result of the war in which we are now engaged. It was considered, however, that this would disclose secrets of design and construction to which the Nation as a whole were not entitled. For my own part I consider that every single detail of the whole of these works should be drawn out and described for the benefit of the entire British Chemical Industry. I look upon this as an absolute right to which the Nation should be entitled. However, I have one or two other slides, very kindly lent to me by Dr. Harker, which will help to point the moral.*

The first is the power house at Saaheim. Next the Badische furnace at Rjukan. Next the interior of the furnace house in the new factory there. And the last the granite absorption towers. These are, of course parts of the nitrogen fixation plants. I give them as reminders that engineering design and construction is figuring more and more in modern chemical processes.

Now I believe it is increasingly necessary for the engineer to take a larger part not only in the design but in the running of this special kind of plant. I do not mean that the control should not be chemical, for I think in the majority of cases, if not all, it must be. But I am convinced that when the conditions are found and laid down, the engineer will be quite capable of carrying them out, while his natural ability for handling men and materials cannot but be most useful assets. For instance, it is quite an easy matter to lay down the conditions of working in, say, an autoclave or a centrifugal, and chemical control should be kept over such operations, but the practical working of the machines, their design and upkeep, and the regulation of the attendant labor, the design of the plant and its best lay-out, having regard to the general conditions of economy and the handling of materials, should in a large degree be left to the engineer, since by training he is the more practical person.

Let Engineer Execute Chemist's Plans.

If we start with the theory that everybody can be

---

*These slides were exhibited at the meeting.

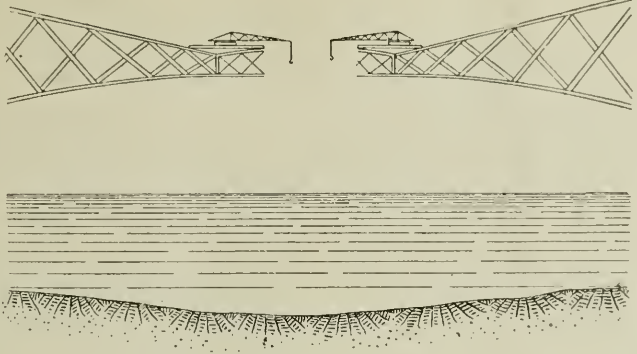

FIG 7.

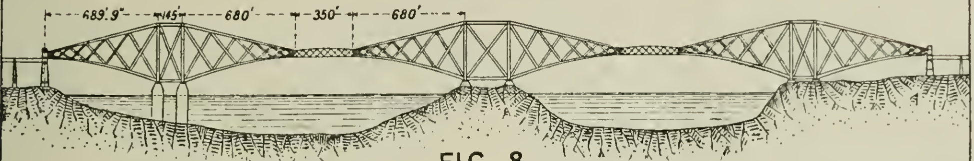

FIG. 8.

trained to be an engineer or a chemist we shall go hopelessly wrong. The function of our teachers should be to ascertain in what direction the mental capacity of each pupil lies, and to direct him to follow the right main road. It would be very easy to put forward a theory in respect of this if one were needed. In the branch of industry with which I am closely associated, I am aware that in the past there has been much lack of progress through the engineer not deciding to take the chemist into his counsel, but I am also sure of this, that had the chemist been substituted without on his part taking the engineer into his counsel we should have been no further forward. The case is essentially one for their working in harmony toward the common goal of perfection. I cannot but think, too, that British chemical industries have been to some extent partly sterilized by the narrow spirit in which some chemical manufacturers have regarded their operations. In my opinion, progress as a whole will be best achieved by them, not by hiding from everybody broad principles of design and working, but by placing reliance upon scientific knowledge and experience to keep themselves in the forefront of their competitors. The general principles of ship construction, of bridge making, and of engine building, to take one or two examples, are open practically to every apprentice engineer, who thus grows up in a general atmosphere of such employment which is of untold value to him if he has ability or opportunity to rise above his fellows and to specialize in any particular direction. And yet there are secrets in ship-building, in bridge-making, and in engine-designing, just as there are in the various chemical industries. The need of such men so trained is now becoming a national one and the full story of their serious shortage cannot yet be told.

Two Fields Separate, Yet Complementary.

If we are to maintain our position among the Nations, we must in this respect make a radical change of our pre-war methods. A well-known engineer of wide reputation spoke to me not so very long ago of "those stupid chemists!" and an able Professor of Chemistry said in my hearing, more recently, that "Engineers were such stupid people!" Neither profession deserves such reproaches. The engineer should be taught sufficient chemistry to be able to appreciate the chemist's point of view, and the chemist should know enough of engineering to realize that with the engineer thus trained he can leave the practical application of the processes he devises in the laboratory and supervises in the chemical works.

I have had costly experience of the engineer working in a water-tight compartment of his own, and of the chemist doing likewise. Both courses result in inefficiency. The plan I have found to meet all such difficulties is to organize two distinct staffs under the headship of a chemist on the one hand, and of an engineer on the other, who consult with each other and work together in overcoming the difficulties which daily confront them. I should be sorry to go back to any other system. Chemists and engineers may, I think, be looked upon as the physicians and surgeons of industry, with their respective parts to play in building up and maintaining in increasing strength the well-being of chemical science, and extending its usefulness in the service of man.

THE PREPARATION OF PICRIC ACID AND OTHER NITRATED PHENOLS

By Carleton Ellis, Louis Rabinovitz and A. A. Wells*

Experiments in Connection with a Method for the Production of Picric Acid from Chlorbenzol Are Here Described—In Employing the Dinitrochlorbenzol Process, the Writers Obtained, After the Preliminary Preparation of Three Intermediates, Picric Acid of High Purity Without Resorting to Recrystallization.

THE recent demand for picric acid as an explosive and for use in the dyestuff industry has given a marked impetus to the manufacture of this material.

Picric acid may be obtained by the action of strong nitric acid on various organic compounds such as indigo and certain vegetable resins, etc. Such methods, however, in the main are only of scientific interest and are not considered feasible for the manufacture of picric acid on a large scale. The standard process for preparing picric acid on a commercial scale involves the use of phenol. This method has long been known and has been thoroughly studied, and needs but little comment, as the literature on this subject is very comprehensive. In brief, the usual method consists in sulphonating pure phenol by reacting on it with concentrated sulphuric acid until completely soluble in water, and subsequently nitrating the phenol sulphonic acid thus obtained with nitric acid of about 1.3 sp. gr. Such a procedure is, of course, subject to a number of variations.

At the present time a considerable amount of the phenol used in the manufacture of picric acid is prepared directly from benzol. This is due to the limited supply of phenol from coal tar available on the market. The preparation of phenol from benzol is a lengthy operation involving sulphonation and a caustic soda fusion. The number of steps required and the losses in each step render the method a costly and somewhat difficult one.

Benzol to Picric Acid by Another Route.

The writers have devoted a considerable amount of study to the production of picric acid from benzol by another route—namely, benzol ⟶ chlorbenzol ⟶ dinitrochlorbenzol ⟶ dinitrophenol ⟶ picric acid, and some of the results obtained are of interest from a number of standpoints.

In connection with the preparation of picric acid by the methods described below a brief outline will be given of the reactions involved:

Benzol in the presence of a catalyzer and under proper conditions acts according to the following reaction:

1. $C_6H_6 + Cl_2 = C_6H_5Cl + HCl$.

Chlorbenzol on nitration gives mononitrochlorbenzol (ortho and para), or dinitrochlorbenzol depending upon the intensity with which the nitration is carried out. The reactions are as follows:

2. $C_6H_5Cl + HNO_3 = C_6H_4NO_2Cl + H_2O$.
3. $C_6H_5Cl + 2HNO_3 = C_6H_3(NO_2)_2Cl + 2H_2O$

The mixture of ortho and para nitrochlorbenzols obtained by reaction (2) can be hydrolyzed under pressure with caustic soda giving the corresponding sodium nitrophenates.

4. $C_6H_4NO_2Cl + 2NaOH = C_6H_4NO_2ONa + NaCl + H_2O$

The hydrolysis with alkalies of the dinitrochlorbenzol can be carried out at atmospheric pressure, and is represented by the following reaction:

5. $C_6H_3(NO_2)_2Cl + 2NaOH = C_6H_3(NO_2)_2ONa + NaCl + H_2O$

The salts of these nitrophenols, which are readily soluble in water, are acidified in order to set free the phenol.

6. $C_6H_4NO_2ONa + HCl = C_6H_4NO_2OH + NaCl$
7. $C_6H_3(NO_2)_2ONa + HCl = C_6H_3(NO_2)_2OH + NaCl$

These nitrophenols on further nitration are converted into picric acid.

8. $C_6H_4NO_2OH + 2HNO_3 = C_6H_2(NO_2)_3OH + 2H_2O$
9. $C_6H_3(NO_2)_2OH + HNO_3 = C_6H_2(NO_2)_3OH + H_2O$

EXPERIMENTAL.

CHLORBENZOL.

The apparatus used for making chlorbenzol consisted of a steel tank having a cooling coil and an agitator. This tank was fitted with an inlet pipe for the introduction of chlorine and an outlet pipe for hydrochloric acid. The outlet pipe was connected to an absorber containing water in which the hydrochloric acid was collected. The tank was also fitted with a riser pipe to serve as a rectifying column and connecting to a water cooled condenser. The operation of the apparatus was as follows:

Benzol mixed with about one-half per cent. of iron catalyzer was introduced into the tank, and chlorine was bubbled through it at a fairly rapid rate. The agitator was run rather rapidly in order to prevent local heating. This is necessary, for if the benzol becomes hot, a large amount of dichlorbenzol is formed, and the dichlor compound is objectionable for the present purposes. The chlorine gas employed was supplied from cylinders of liquid chlorine. The chlorine cylinder was placed on a scale and connected by means of a flexible hose. In this way the rate of flow could be controlled, and the end of the operation indicated when the predetermined amount of chlorine had been passed in. As soon as this point was reached the chlorine was turned off and steam turned into the coil.

---

*Consulting Chemists and Chemical Engineers, 92-98 Greenwood Ave., Montclair, N. J.

Removal of Acid Fumes.

During the first experiment no special precautions were taken to collect the hydrochloric acid which was dissolved in the chlorbenzol, and as soon as heat was applied acid fumes came off in great quantities. In later experiments a U trap was placed at the end of the condenser and a vent pipe for the hydrochloric was inserted between the trap and the condenser. The acid fumes were then led off and no more trouble was encountered in this way. It was found on distillation in the chlorination apparatus that the rectification of the chlorbenzol was not efficient, but that further purification was necessary. The fractions obtained from this distillation were separately redistilled in a laboratory still using a fractioning still head, and the combined results indicated a total yield of materials approximately as follows:

Unchanged benzol 15 per cent.
Monochlobenzol 15 per cent.
Dichlorbenzol 10 per cent.

As the unchanged benzol can be returned to the apparatus and treated with more chlorine, it is feasible to obtain yields up to 85 to 90 per cent. of monochlorbenzol. The temperature, however, must be maintained fairly low, best below 20°C.

MONONITROCHLORBENZOL METHOD.

Another method for the preparation of picric acid from chlorbenzol involves the following steps: (1) The conversion of chlorbenzol into a mixture of ortho and para mononitrochlorbenzol by means of a mixture of nitric and sulphuric acids. (2) The hydrolysis of this mixture of nitro products under pressure with aqueous sodium hydroxide. (3) The liberation of the ortho and para mononitrophenol from their corresponding sodium salts by means of acid. (4) The conversion of these mononitrophenols into picric acid.

Mononitrochlorbenzol is readily obtained by the action of a mixture of commercial sulphuric acid (66° Bé) and nitric acid (39° Bé) on monochlorbenzol. The following illustrates the method of preparation:

One part (by weight) of chlorbenzol was gradually added to three parts (by weight) of a mixture of equal parts (by volume) of sulphuric (sp. gr. 1.8) and nitric acid (sp. gr. 1.43). In order to check the violence of the reaction it was necessary to cool the reaction vessel by immersing it in cold water during the introduction of chlorbenzol into the acid mixture. The oil was then separated from the spent acids, washed and dried. A yield of about 95 per cent. of the theoretical was obtained. By several crystallizations from alcohol it was found that the mixture was made up of about 48 per cent. of the para compound, melting at 81°C. (Melting point given in the literature is 83°C.), and 52 per cent. ortho derivative, which melted at 28°C.

Pressure for Conversion to Sales.

One part of the mixed nitrochlorbenzols was heated in an autoclave for 4 hours at 60 pounds pressure, with one part of sodium hydroxide and 20 parts of water. The conversion of the nitrochlorbenzols into the sodium salts of the nitrophenols was practically quantitative. The amount of tar formed was slight, and the sodium salts on cooling crystallized out as well defined needles. The use of more concentrated solutions of sodium hydroxide in the hydrolysis is not advantageous, as they tend to form considerable amounts of tarry bodies.

Milk of lime was used in several experiments in the place of sodium hydroxide solution, but without success, the nitrochlorbenzols being recovered practically unchanged.

Mononitrochlorbenzol was boiled at atmospheric pressure with a large excess of a concentrated solution of sodium hydroxide. With the exception of a slight amount of resin formation the action of the alkali was negligible.

In those experiments where the tar formation was most marked it was observed that only a small amount of ortho nitrophenol was obtained on distilling the mixed nitro phenols. This would seem to point to the fact that the ortho derivative is more prone to decompose than the para compound. This fact, however, has not been definitely established.

The liquid from the autoclave was filtered, acidified cautiously with dilute acid, cooled and treated with sodium chloride to saturation to separate the nitrophenols.

The conversion of the nitrophenols into picric acid was effected as follows: One part of the mixed mononitrophenols was treated with eight parts of an acid mixture consisting of one part nitric acid (1.42) and three parts sulphuric acid (66°Bé). The addition of the acids was made gradually under cooling and agitation. The mixture was then stirred for three hours at room temperature. The temperature of the nitrating mixture rose during this operation to 90°C. The liquid was poured into cold water and the picric acid was filtered, washed and dried. The product obtained was good in color and free from resinous bodies. The melting point was 120°C. The yield was approximately quantitative.

DINITROCHLORBENZOL METHOD.

The dinitrochlorbenzol process for the manufacture of picric acid directly from benzol consists of the following principal steps: (1) The conversion of benzol into chlorbenzol by means of chlorine and a chlorine carrier; (2) the nitration of the chlorbenzol to dinitrochlorbenzol by means of sulphuric and nitric acids, or sulphuric acid and sodium nitrate; (3) the hydrolysis of the resulting dinitrochlorbenzol with sodium hydroxide, sodium carbonate or calcium hydrate; (4) the acidification of the dinitrophenate solution; (5) the further nitration of the dinitrophenol thus obtained to picric acid. Each one of these steps is simple, the yields in most cases are almost quantitative, and the apparatus required in carrying out these steps is not elaborate.

Results of Various Methods.

In the matter immediately following a number of laboratory observations on the nitration of chlorbenzol are noted:

One part (by weight) of chlorbenzol was slowly run into a cooled mixture of three parts of fuming sulphuric acid (20 per cent. free SO_3) and two parts of nitric acid (sp. gr. 1.42), and the mixture was heated under reflux condenser and stirred for two hours. The temperature of the mixture was gradually brought up during this time to 160°C. It was then poured into ice cold water, and the solid dinitrochlorbenzol which had formed was washed free from acid and dried. The product obtained melted at 48°C. 1, 2, 4—dinitrochlorbenzol melts at 51°C. The yield obtained was about eighty per cent. of the theoretical. Any appreciable decrease in the amount of the nitric or sulphuric acid employed gave a dinitrochlorbenzol contaminated with the mononitro compounds, the amount of the latter increasing as the amount of acids used was decreased.

The experiment was repeated, the temperature being kept at 100°C. The product obtained under this change of conditions consisted largely of a mixture of ortho and para mononitrobenzol.

Fifty parts (by weight) of nitric acid (sp. gr. 1.42) and fuming sulphuric acid, and 25 parts of chlorbenzol mixed with the usual precautions and heated for three hours, with stirring, under reflux condenser at 160 to 170 C. gave seventeen parts of pure dinitrochlorbenzol and twenty parts of oily material, which consisted of a mixture of ortho and para nitrochlorbenzol and some dinitrochlorbenzol.

A mixture of fuming nitric acid (sp. gr. 1.6) and commercial sulphuric (66°Bé) gave satisfastory results. One part (by weight) of chlorbenzol and three parts each of fuming nitric acid (sp. gr. 1.6) and of ordinary sulphuric acid heated under reflux and stirring for three or four hours gave a dinitrochlorbenzol, which contained only traces of the mononitro product. The yield of dinitrochlorbenzol as obtained by crystallization from alcohol was fully seventy-five per cent.

A mixture of 66 sulphuric acid and nitric acid (sp. gr. 1.42) reacted with chlorbenzol to give a heavy oil which did not crystallize on standing. This oil was found to contain mononitrochlorbenzol and small amounts of dinitrochlorbenzol

Use of Chile Saltpetre Possible.

The preparation of a fairly pure dinitrochlorbenzol was readily effected by the use of sodium nitrate and commercial sulphuric acid. It was not essential that the sodium nitrate should be pure, as it was found that Chile salpetre gave satisfactory results In the case of Chile salpetre, however, it was considered advantageous to allow the sulphuric acid to act on the sodium nitrate for a short time before introducing the chlorbenzol, as chlorine, liberated from any sodium chloride present in the crude sodium nitrate under these conditions, might effect a further chlorination of the chlorbenzol. A nitration mixture which gave good results was prepared from three parts of sodium nitrate and six parts of commercial sulphuric acid (66°Bé). To this mixture one part of chlorbenzol was slowly added, and the reaction mass was kept at a low temperature by water cooling. The nitration was carried out under a reflux condenser and continuous stirring. The temperature was raised very slowly in order that the evolution of nitric oxide fumes might not become too vigorous, as this would result in a loss of nitric acid and an incomplete nitration. In the case of experiments carried out on a small scale, nitration was completed in four hours. The temperature during the first hour was maintained at 85 to 100°C., during the second and third hour at 130°C., and at 140 to 160°C. during the last hour. Investigations on a larger scale showed that it was unnecessary to employ such high temperatures. On the other hand the time in that case is advantageously extended considerably. Thus, in one test, 138 lbs. of 66°Bé sulphuric acid were added slowly to 56 lbs. of Chile salpetre, and the mixture was agitated in a jacketed iron kettle provided with a cover, reflux condenser and heavy iron stirrer, until the odor of chlorine was no longer noticeable. The chlorbenzol was then added slowly under constant cooling. The mixture was heated to about 90°C., and maintained at 90 to 100° for about five hours, at 110° for nine hours and at 130 to 136° for ten hours, making a total nitration period of twenty-four hours. A yield of upward of ninety per cent. of the theoretical was obtained. The product contained traces only of mononitrochlorbenzol.

Dinitrochlorbenzol has a very irritating action on the skin, and should therefore be handled with caution.

Dinitrophenol.

The hydrolysis of dinitrochlorbenzol by means of sodium carbonate was found to be a slow procedure. For example, 1 part by weight of dinitrochlorbenzol was heated under reflux condenser for eight hours with a boiling solution of two parts sodium carbonate in fifteen parts of water. About 40 per cent. of the dinitrochlorbenzol remained unchanged. Experiments with 20 per cent. and 30 per cent. solution of sodium carbonate failed to completely hydrolyze the dinitrochlorbenzol even on fairly prolonged boiling.

Solutions of sodium hydroxide split off the chlorine from dinitrochlorbenzol much faster and probably more completely than solutions of sodium carbonate. Two parts (by weight) of dinitrochlorbenzol were heated under reflux condenser and stirred, with a solution of one part of sodium hydroxide in nine parts of water, for a period of about an hour and a half. At the end of this time the dinitrochlorbenzol was completely hydrolyzed. Small amounts of mononitrochlorbenzol usually accompany the dinitro compound. The former compound was not affected by the alkali, and was removed in this case by blowing steam through the solution until the vapors were free from the odor of mononitrochlorbenzol. The hot solution of sodium dinitrophenate was then filtered to remove traces of the flocculent material. On acidifying the solution, the 1.2.4 dinitrophenol separated as a brownish crystalline precipitate. Experiments were carried out with more concentrated solutions of sodium hydroxide than that employed in the preceding, but difficulties were encountered with the more concentrated solutions, because a portion of the sodium dinitrophenate crystallized out from the hot liquors, even on slight cooling, rendering the material troublesome to handle.

Hydrolysis with Slaked Lime.

The hydrolysis of dinitrochlorbenzol with freshly slaked lime is best carried out in the presence of a large excess of water. The operation requires more time than the hydrolysis with sodium hydroxide. Stirring, reflux condenser and steam distillation for the removal of the steam volatile impurities are necessary, as in the case of sodium hydroxide. Five parts (by weight) of dinitrochlorbenzol, two parts of freshly slaked lime and one hundred parts of water were boiled under reflux condenser for 3¼ hours while subjected to continuous agitation. After an hour or so a voluminous precipitate of basic calcium dinitrophenolate was formed. This precipitate redissolved after an hour or two of boiling so that at the end of the treatment there was present only a slight precipitate. The solution was filtered, steam distilled and acidified with hydrochloric acid. The dinitrophenol obtained was light in color, but the melting point was low (108°C.) The pure calcium salt of dinitrophenol resembled the sodium salt in physical appearance. It was readily soluble in water and easily converted into an insoluble salt, apparently of a basic nature, on washing with large amounts of water. Care should be exercised in handling salts of dinitrophenol, sodium dinitrophenate, for example, when brought in contact with a flame will explode with marked violence.

Operations on Large Scale with NaOH.

The hydrolysis on the large scale of dinitrochlorbenzol offered no special difficulties. The dinitrochlorbenzol was placed in a capacious iron kettle provided with a closed steam coil, a live steam coil, a stirrer of the propeller type, and a reflux condenser. Two draw-offs were provided, one on the side of the kettle about six inches from the bottom from which the major portion of the solution was drawn, and the other on the bottom from which the residues, which are not hydrolyzed by the caustic solution and not volatilized by steam, are drawn off. A solution of 50 lbs. of caustic soda in 100 gallons of water was added to the dinitrochlorbenzol, and the mixture boiled for 2½ hours. Live steam was then run in for about one hour, or until the steam from the outlet pipe was practically odorless. An appreciable amount of oil was blown over with the steam.

A slight excess of 10 per cent. H_2SO_4 was placed in a tank provided with a slowly revolving wooden stirrer. The clear solution of sodium dinitrophenate from the hydrolyzer was then run into the acid solution in a slow stream under agitation. This method of precipitating the dinitrophenol insured a light colored product of good melting point. A somewhat darker colored product was obtained on adding the liquids in the reverse order. The yield by this method was about 93 per cent.

Acidification of Dinitrophenol.

The conversion of dinitrophenol into picric acid introduces no special difficulties. Experiments on the small scale showed the addition of the third nitro group to be a readily controlled reaction. Large scale experiments did not give any new complications. One part (by weight) of dinitrophenol and two parts of 66° Bé sulphuric acid were placed in an earthenware crock set in a sulphuric acid bath, which, by means of a coil of lead pipe, could be heated and cooled at will. The mixture was cooled and one part of nitric acid was added. The temperature was raised very slowly to 100-110°C. and maintained for three hours. The mixture was then poured into cold water, the picric acid was filtered through cloth filters and washed with a small amount of cold water. The picric acid obtained was good in color and melted at 120°C. At 295°F. the liquid fusion of the picric acid was slightly brown in color.

Conclusion.

Regarded as a whole the dinitrochlorbenzol process for the manufacture of picric acid compares favorably with the process involving such a complicated procedure as the preparation of pure phenol from benzol. Starting with a fairly pure chlorbenzol such as is available on the market in considerable quantities one can arrive at a product of high purity without resorting to recrystallization. This is of interest when one considers that three intermediate compounds are prepared before picric acid is finally obtained from chlorbenzol, and that crude sodium nitrate and commercial sulphuric acid are used in the process.

Such impurities as benzol or mononitrochlorbenzol resulting from imperfect fractionation or incomplete nitration of the chlorbenzol are eliminated during the hydrolysis of the dinitrochlorbenzol.

Direct Method.

An interesting process of preparing picric acid directly from benzol is that of Wolffenstein and Böters (German Patent 194,883, 1907) who prepared picric acid directly from benzol using mercuric nitrate as a catalyzer. A mixture of 400 grms. of benzol, 1,350 grms. of nitric acid (sp. gr. 1.39) and 50 grms. of mercuric nitrate are stated to give 380 grms. of picric acid, 160 grms. of nitrobenzol and 2 grms. of orthonitrophenol. Some work carried out in this laboratory along this line did not meet with much success. A large amount of resinous material formed The yields of picric acid obtained by this process were never above fourteen per cent In one experiment 25 grms. of mercury were dissolved in an excess of

AMERICAN DYES—AFTER THE WAR

Will This Industry Be Able to Maintain Its Foothold?*

By B. R. Armour

B. R. ARMOUR.

Some of the Non-Technical Phases of the American Dye Situation Are Discussed by the Writer, Whose Views, Because of His Knowledge of the Subject, Should Be of Interest to Every Chemist and Manufacturer Connected with the Industry. Herein Is Described the Sort of Competition We May Look for After the War, and Suggestions Regarding Tariff Legislation Based on Standards of Concentration Are Given. Incidentally, in the Factory of American Aniline Products, Inc., Harrison, N. J., Which Mr. Armour Represents, None But American Chemists, Born and Trained in This Country, Are Employed.

IN the past, the German manufacturers of dyestuffs have effectively controlled the Swiss manufacture by supplying the latter branch of the industry with its intermediates. Take, for instance, the color Sky Blue, which we have succeeded in developing. It is produced from the base known as dianisidine. The production of dianisidine is an intricate and expensive process, involving the smelting and refining of zinc. The Swiss color factories did not attempt to make dianisidine, but procured it from the German dye plants, who supplied it under an agreement whereby they could control the price at which the Swiss manufacturers sold Sky Blue. This price was a fair one to the Swiss, giving them a profit of 50 per cent. But, due to the greater production of the color in German plants and its resulting lower cost of manufacture, this price gave the German manufacturers a profit of 100 per cent. By this method the German monopoly virtually controlled the Swiss industry, showing us the sort of competition we can expect after the war.

Fight Will Be Bitter.

In fact, against our concern this competition has already begun. We are the only American dye company specializing in the intricate, expensive colors, having developed a line that will be complete for all fibers in the textile industries by the end of January, 1917. When the *Deutschland* made her first trip to the United States she learned that we were producing these expensive colors, which were, in general, the sort of colors she brought with her, the German manufacturers being aware that the development of the cheaper colors in this country had progressed on a large scale since the war started.

Her cargo instantly met with our competition, and the result was that on her second voyage she brought large quantities of these dyes and proceeded to cut our prices, attempting to weaken us during the progress of the war by ruinous competition. Naturally, in the production of such colors as we are making, the development is slow and our first costs high. The *Deutschland* on her first trip brought no Victoria Blue, an expensive color. When the German manufacturers learned that we were producing this color they shipped practically all the Victoria Blue left in Germany on the second voyage of the *Deutschland*.

The Swiss Colors Co. was organized in 1907 as importers. American Aniline Products, Inc., was organized in 1914 to engage in manufacture. At the beginning a number of chemists of foreign birth and training were employed, but certain mysterious factory experiences, which almost proved disastrous to the new concern, led its heads to believe that their chemists wished them no good luck in their enterprise.

We are certain that one of our chief employes in those first months of our undertaking, if not actually in the pay of the foreign dyemakers, was at least in accord with their policy not to allow competition to develop in other lands. We noticed it in our yields, which continued to be away below normal, without visible progress being made toward better results. These processes are so expensive that unless they early begin yielding dyes in large quantities they might easily ruin the firm which is paying for them. We discovered this unsatisfactory condition in time to save ourselves, and since then we have em

*From the Washington "Observer"

(Continued from page 25.)

nitric acid of 1.39 sp. gr. and this solution was then treated with 200 grams of benzol and 100 c.c. of nitric acid of the same strength. The mixture was then heated for several hours on a steam bath under reflux and then steam distilled until the distillate was practically free from nitrobenzol. The residue in the flask after three successive crystallizations carried to remove the resins gave about 13.6 per cent of picric acid melting at about 117 C. Various other bodies were tested as catalyzers in place of mercury, but without success. Among the substances tested were the nitrates of uranium, cadmium, bismuth, chromium and cerium; also chromic, molybdic and vanadic acids. In no case was there obtained more than a trace of picric acid. The general procedure was to mix 8 parts of benzol, 1 part of the substance to be tested as a catalyzer and about 30 parts of nitric acid (sp. gr. 1.39) and to boil the mixture on a hot water bath under reflux condenser until there was no further evolution of red nitric oxide fumes. The product was steam distilled in order to separate nitrophenol and the unchanged benzol from the picric acid. Chlorbenzol was nitrated with 5 parts of nitric acid (sp. gr. 1.4) in the presence of small amounts of mercuric nitrate without obtaining any picric acid or picryl chloride. Nitrating experiments carried out on nitrobenzol and dinitrobenzol in the presence of mercuric nitrate also failed to give picric acid.

ployed none but American chemists, born and trained in this country. We have had some difficulty in curbing the enthusiasm of these young fellows. American-like, they are apt to become fascinated by the possible uses of by-products and turn aside from the main lines of investigation which they are following up. But they have brought our yields up to standard.

I wish to correct the impression that American dyemakers have been reaping huge profits from the war. Wages are so high and crude materials so expensive that the profits have not been anywhere near as much as the selling prices might indicate. Moreover, these profits in large part have been immediately invested in plants—the American dyemakers have been working for a manufacturing apparatus, which will be of inestimable permanent value to this country in the future.

Domestic Industry Not Yet Secure.

I do not by any means regard the domestic market as conquered by the domestic manufacture. It is evident that, in spite of the good satisfaction which our domestic dyes are giving, the American color users, in large part, expect to get their colors in the future where they can buy them cheapest. If because of an inadequate protection in the tariff the German producers are able to undersell us, they will get the business back again. The recent peace flurry showed that we are not as secure as some of our manufacturers supposed. The peace talk in December absolutely upset the color market. No contracts could be made as long as there seemed to be a chance for peace, and our sales dropped away off. I know of one firm in this country which had been buying colors at the rate of $10,000 a month. In December this concern refused to buy any colors except at ruinously low prices.

For the next year, at any rate, the prosperity of the domestic industry will depend upon the continuance of the war. At the end of that time we may have improved our factory efficiency to the point where we can offer competition in certain lines. But, even then, we cannot expect to maintain a complete industry in this country unless we get more tariff legislation. As far as this company is concerned, we are setting aside every dollar we can spare from our actual factory needs to form a reserve to tide us through the critical period following the war.

New Dye Tariff Insufficient.

The new dye tariff enacted by Congress is insufficient in many particulars. The specific rate of 5 cents a pound added to 30 per cent. *ad valorem* is not nearly enough to protect the more expensive colors, the specific rate amounting to an equivalent of 10 per cent. or less *ad valorem,* a very slight increase in protection over the old rate, which was entirely inadequate, as the state of the industry showed. What we need, in my opinion, is a sliding scale of specific duties, graduated so as to give an equal amount of protection to all colors.

Then I believe that the government should establish standards on which the duties should be based. For instance, the standard of Scarlet, as it is now in use and as it has been imported in the past, is only one-third of the strength to which this color can be concentrated. Undoubtedly the importer of the future will bring in his color three times as strong as in the past, cutting the specific duty to one and two-thirds cents a pound, instead of the five cents which Congress intended. Many other colors can be concentrated to evade duty and then reduced again with neutral substances after they have been imported. In future tariff making we should list colors according to groups and figure the tariff rate on the highest possible concentration.

AMERICAN COLOR MAKERS PRODUCE OWN INTERMEDIATES

One of the pleasing results of the temporary throttling of the American dye industry by the European war is the recent achievement of the Sherwin-Williams Company, which, with the aid of a corps of chemical engineers, has developed and erected a plant at Kensington, Ill., for the production of intermediates which were previously imported. Their initial step was the manufacture of Beta Naphthol and Paranitraniline, for which they had previously been obliged to look to foreign producers. They have also been successful in the commercial production of Metanitroparatoluidine and Paranitranilinesulfonic acid, from which are manufactured Helio Fast Red R and Lake Red P. All organic chemicals are manufactured from refined coal tar products, Benzol, Toluol, Zylol and Naphthalene, and in the utilization of their by-products they have also engaged in the manufacture of Glacial Acetic Acid.

ONE FORMULA—104 COLORS, IS ACHIEVEMENT OF DR. WOLF

The recent perfection of a formula which, it is said, will develop all colors and black, and will render American dyes absolutely fast, giving them a brilliance equal to the German dyes available before the war, has been announced by Dr. Willy Wolff, chief chemist of the Phoenix Knitting Works. In experiments, 104 colors have been developed from this formula.

In a statement to the press, Dr. Wolff said: "The impression should not prevail that I have succeeded in making a new kind of dyestuff. What I have done is to discover a certain combination of chemicals, all made in this counrty, which will simplify fabric dyeing and produce better results with less dye materials. Dyemakers have experimented for years to 'develop' direct colors, but, so far as I know, this is the first time it has been successfully and commercially accomplished."

THE ESTIMATION OF FREE ACIDS IN SOLUTION

Methods for the Determination of Uncombined Sulphuric, Nitric and Picric Acids in the Presence of Each Other.

By F. W. Richardson, F. I. C.*

Experiences Encountered While Determining the Acids Present in Effluents from Picric Acid Works Led the Writer to Abandon Solvent Processes in Favor of Colorimetry, the Pure Yellow Color of Picric Acid Solutions Being Easily Comparable With the Yellow Units of Lovibond's Tintometer.

THE estimation of sulphuric and nitric acids in the presence of each other presents no special features, and good results may be obtained by well-known methods. The entrance of the third factor, picric acid, creates difficulties. Effluents from picric acid works contain much sulphuric and but little nitric acid, with some picric acid from the wash liquors obtained in the subsequent purifying processes.

In pure solutions picric acid can be very easily estimated. The hydroxyl group gives to the acid the characteristics of quite a strong univalent acid. As the molecular weight of picric acid is 229, 1 c.c. of decinormal alkali is equivalent to 22.9 milligrams of the acid, an undesirably large figure when the analyst is dealing with minute amounts. In a direct titration of 70 c.c. of an effluent 0.1 c.c. of N/10 alkali would represent 2.29 milligrams or 2.29 grains per gallon of the acid.

Methyl Red Is Good Indicator.

I find that while phenolphthalein and methyl orange are good indicators for picric acid, methyl red is more delicate than either. I cannot agree with Minovici and Kollo that the use of phenolphthalein requires an excess of alkali to give the end point. Nevertheless these chemists are right in recommending methyl red (p-dimethylaminoazobenezene-o-carb-oxylic acid). The end-point is very sharp—the passage from bright red to orange and from orange to pure yellow requires only two drops of decinormal alkali. Iodo-iodate of potassium has been recommended by Sanders:

$$6C_6H_2(NO_2)_3OH + 5KI + KIO_3 = 3H_2O + 6C_6H_2(NO_2)_3OK + 3I_2$$

One molecule of the acid liberates one atom of iodine; therefore the value of 1 c.c. of the thiosulphate is exactly that of 1 c.c. of decinormal alkali. Leo Schwarz finds that complete reaction only occurs when the solution has been heated for some time in a closed vessel at 100° C.

I have found that 0.5 grams of picric acid in 100 c.c. of aqueous solution at 15° C. required 13.5 c.c. of N/10 thiosulphate, equivalent to only 0.309 grams or 61.8% of the picric acid taken, and that the heating process described by Schwarz was necessary. For several reasons the use of iodo-iodate is not to be recommended. The delicacy is no greater than that of methyl red. Heat is required and iodine is volatile. During the heating process free iodine acts upon organic matters present in effluents and introduces a loss, minimizing the true proportion of picric acid.

Benzol and Ether Undesirable Solvents.

I have tried to utilize the well-known properties of such liquids as benzol and ether for dissolving picric acid, but the results have not been encouraging. Benzol is troublesome on account of the readiness with which it forms emulsions. Ether dissolves so much water that repeated washings with water are necessary, and the peculiar manner in which picric acid passes from ether to aqueous liquid, and vice versa, is most disturbing. Moreover, most stream and river waters polluted with the effluents from picric acid works contain only very small amounts of the acid itself, say from 1 to 3 grains per gallon. I have therefore abandoned solvent process and have resorted to colorimetry. Picric acid solutions have the great advantage of being pure yellow, and are easily comparable with the yellow units of Lovibond's tintometer.

One hundred parts of cold water dissolve about 0.6 part of picric acid; this represents about 420 grains of the acid in a gallon of water. A solution containing only 2 parts of the acid in a million parts of water or 1/7 grain of the acid in a gallon can be readily matched as to its yellow color in a one-inch cell. By using much longer cells quantities as little as 1/50 grain of picric acid in a gallon can be matched, and therefore estimated.

It is not very troublesome to work out charts giving the values of thicknesses of picric acid solutions varying from 1/8 of an inch to 24 inches. In the case of the longer cells I use the special arrangement devised by Mr. Lovibond. To avoid complications I use a glass cell which happens to give 23/25 of an inch thickness of liquid.

Color Depth Increases with Temperature.

I do not recommend a greater range of units than from 0.5 to 6.0. By dilution or concentration it is very easy to bring the color depth within these limits. One very necessary caution must be made; the color depth of picric acid solutions increases very considerably with rising temperature. The following chart shows the increase in color depths from 0° C. to 60° C., the units increasing from 3.7 to 6.1. From 10° C. to 20° C. the color increases from 4.05 to 4.5 units.

---

*From the Journal of the Society of Chemical Industry. Presented at a meeting of the Yorkshire Section in Leeds, England.

Table A.

Increase of Color-depth on Heating a Dilute Solution of Picric Acid, Using Lovibond's Tintometer.

TABLE A.

C.	Yellow Units.	C.	Yellow Units.
0	3.7	25	4.7
5	3.85	30	4.9
10	4.05	50	5.7
15	4.30	60	6.1
20	4.50		

I have used 15 C. as the most convenient, or the least inconvenient, temperature. In the summer months, particularly in July and August, a scale of unit-values for 20 C., or even 25 C., should be used. This scale can be made in a few minutes.

The following table (B) gives the color-depths of picric acid solutions in a glass cell of 23/25 inch internal diameter. By a direct reading, obtained in a few moments, the amount of picric acid can be estimated when varying from 1.25 to 60 parts per million or 0.0875 to 4.2 grains per gallon.

TABLE B.

Color values of dilute solutions of picric acid in a 23/25-inch glass cell (Lovibond's units).

Yellow units.	Grains of picric acid per gal.	Yellow units.	Grains of picric acid per gal.	Yellow units.	Grains of picric acid per gal.
0.3	0.0875	2.1	0.90	3.5	1.61
0.6	0.1750	2.2	0.92	3.6	1.68
0.8	0.2800	2.3	0.95	3.7	1.82
1.0	0.35	2.4	0.98	3.8	1.84
1.1	0.39	2.5	1.05	3.9	1.86
1.2	0.42	2.6	1.09	4.0	1.89
1.3	0.49	2.7	1.12	4.1	2.03
1.4	0.53	2.8	1.19	4.2	2.10
1.5	0.56	2.9	1.33	4.3	2.16
1.6	0.59	3.0	1.37	4.4	2.24
1.7	0.63	3.1	1.40	4.5	2.31
1.8	0.67	3.2	1.43	4.6	2.38
1.9	0.70	3.3	1.47	4.7	2.45
2.0	0.875	3.4	1.54	4.8	2.52

I find that this chart is sufficient for most stream, river or canal waters containing picric acid effluents. By concentration or dilution to fixed volumes any picric acid solution can readily be brought within this range.

I estimate the nitric acid by phenoldisulphonic acid in the well-known manner with certain modifications, using the table given by Hollings and myself.[3] I have worked out a table giving the values of the color depths in a one-inch (really 13/14 inch) Lovibond cell from 0.1 unit to 6.2 units of yellow, representing a range of 0.002 to 0.139% of nitric nitrogen in the diluted yellow solution (Table C).

An actual example of working may be of value.

Known amounts of the three acids were used in such dilution as fairly to represent a canal or river water containing effluents from picric acid works.

(1) 70 c.c. of the solution when tinged with methyl red required 6.9 c.c. of N/10 sodium hydroxide for neutralization.

(2) 10 c.c. of the solution after mixing with 5 c.c. of N/10 sodium hydroxide was evaporated to dryness on the water-bath. The residue was well mixed with 1 c.c. of phenoldisulphonic acid mixture, and after warming gently for about five minutes the acid liquid was diluted with about 50 c.c. of water, transferred to a 100 c.c. flask, made alkaline with ammonia, cooled to 15° C., and diluted to 100 c.c. In the 23/25-inch glass cell the color depth was found to be exactly 2.3 yellow units (Table C).

TABLE C.

Estimation of nitrogen as nitrates by phenoldisulphonic acid. Value of yellow units (Lovibond) in a 13/14-inch cell.

Yellow units.	Mgrms. N. in 100 c.c.	Yellow units.	Mgrms. N. in 100 c.c.	Yellow units.	Mgrms. N. in 100 c.c.
0.1	0.002	2.2	0.050	4.3	0.095
0.2	0.004	2.3	0.053	4.4	0.098
0.3	0.005	2.4	0.055	4.5	0.100
0.4	0.007	2.5	0.057	4.6	1.103
0.5	0.010	2.6	0.059	4.7	0.105
0.6	0.011	2.7	0.062	4.8	0.108
0.7	0.014	2.8	0.064	4.9	0.109
0.8	0.015	2.9	0.066	5.0	0.111
0.9	0.017	3.0	0.069	5.1	0.113
1.0	0.020	3.1	0.070	5.2	0.115
1.1	0.023	3.2	0.072	5.3	0.118
1.2	0.025	3.3	0.074	5.4	0.120
1.3	0.027	3.4	0.077	5.5	0.122
1.4	0.030	3.5	0.080	5.6	0.123
1.5	0.032	3.6	0.082	5.7	0.125
1.6	0.034	3.7	0.0832	5.8	0.128
1.7	0.037	3.8	0.086	5.9	0.130
1.8	0.039	3.9	0.087	6.0	0.132
1.9	0.042	4.0	0.090	6.1	0.135
2.0	0.045	4.1	0.092	6.2	0.139
2.1	0.048	4.2	0.093		

(3) The original solution of the three acids gave a color in the 23/25-inch glass cell equal to 0.8 yellow unit. Reference to the table shows that this is equivalent to 0.28 grain of picric acid per gallon.

The calculation is now simple: 70 c.c. contains 0.28 mgrm. of picric acid, equivalent to 0.0121 c.c. of N/10 NaOH. The nitric nitrogen found was equal to 0.0533 mgrm. in 100 c.c. or 0.0371 mgrm. in 70 c.c., equal to 0.167 mgrm. of nitric acid, representing 10 times (on account of the tenfold dilution) the amount, or 1.67 mgrms. of nitric acid in 70 c.c. of the original liquid.

1.67 mgrm. of nitric acid is equal to 0.2650 c.c. of N/10 NaOH
0.28 mgrm. of picric acid is equal to 0.0121 c.c. of N/10 NaOH

Therefore the combined nitric and
picric acids represent in 70 c.c.. 0.2771 c.c. of N/10 NaOH

The total acidity of 70 c.c. equaled 6.9 c.c. of N/10 sodium hydroxide, hence the acidity due to sulphuric acid is 6.6229 c.c., or 32.48 grains of H_2SO_4 per gallon.

Grains per gal.	Present.	Found.	Error.
Sulphuric acid	32.60	32.48	0.12
Nitric acid	1.76	1.67	—0.09
Picric acid	0.28	0.28	nil.

I give the following example to show the necessity of deducting the requisite number of yellow units from the cell reading obtained in the estimation of the nitric acid:

4.4 units were required to match the yellow color.
0.7 unit was found to match the yellow color of the liquid itself when a similar tenfold dilution was made.

3.7 yellow units were therefore required for the color developed by the nitric nitrogen alone.

Grains per gal.	Present.	Found.	Error.
Sulphuric acid	15.0	14.2	—0.8
Nitric acid	2.5	2.63	+0.13
Picric acid	2.5	2.52	+0.02

---

[3] Journal of the Society, 1903, 616-617.

Only 70 c.c. of the liquid was used for the total acidity and an error of only 0.16 c.c. of the N/10 alkali was required to account for the error of —0.8 grain of sulphuric acid per gallon.

The intensity of the color given by picric acid to water is evident from the fact that when pure water contains as little as the 1/325th grain per pint of picric acid it will require 2 units of yellow to match the color in a 24-inch Lovibond's cell. This represents about 1/36 grain of picric acid per gallon.

My attention was naturally directed to other methods of estimating nitric nitrogen in the mixtures. Unfortunately the Halle zinc-iron and caustic soda method results in the decomposition of some 37% of the picric acid, and cannot be used. Moreover, any nitric nitrogen reduction process, zinc copper couple for example, applied to extremely small amounts of substance requires final Nesslerization of the small amount of ammonia, and no advantage over the phenol-disulphonic acid method can reasonably be expected.

"Nitron" is now unobtainable; moreover it was quoted at about 10s. an ounce before the war. As a 10% solution of the acetate is used in liberal amounts the process is costly. Also nitron precipitation is only applicable to appreciable weights of nitric acid and nitrates. As the total amount of nitric acid in the samples frequently supplied to analysts does not exceed a few centigrams, a gravimetric process is scarcely advisable.

The Action of Dilute Solutions of Sulphuric, Nitric, and Picric Acids Upon Iron.

Waters containing picric acid effluents often come in contact with iron machinery and iron boilers. It has been suggested that even small amounts of nitric acid in the presence of larger proportions of sulphuric acid might produce corrosive effects far greater than the mere acidity might indicate.

Very dilute solutions of sulphuric acid as compared with solutions containing the same molecular equivalents of nitric acid act even more readily upon chemically clean wrought iron surfaces. Strips of wrought iron 3 inches by 1 inch were immersed for three days at 10°—20° C. in 500 c.c. of acid solutions. The following figures show the proportions of iron dissolved:

Acid.	Iron dissolved.
N/250 sulphuric acid	82
N/250 nitric acid	49
Equal parts of N/250 sulphuric and nitric acids	53

With solutions of ten times these acid strengths the amounts dissolved were 529, 512, and 500 respectively, or in the ratios 105.8 : 102.4 : 100.0.

The dilute nitric acid forms a brown-red coating upon the iron sheet, and this, in the case of very dilute solutions, may well prove slightly protective.

When the diluted acids alone and mixed are boiled down upon sheet iron, a copious brown-red coating appears only in the case of the solutions containing nitric acid.

Addition of water with re-evaporation caused a much greater action upon the iron in the case of the nitric acid solutions. The percentages of action in this case were sulphuric acid, 100; nitric acid, 127; mixed acids, 116.

It was evident that hydrolytic action was caused by the evaporation process in the case of the nitrate of iron:

$$Fe_2(NO_3)_6 + 6H_2O = Fe_2(OH)_6 + 6HNO_3.$$

The nitric acid set free again acts upon the iron.

Nitric acid solutions when concentrated in boilers will therefore produce extensive corrosive action.

Picric acid of N/250 strength (0.0916% equal to 64.12 grains per gallon) readily acts upon iron. My experiments show that as compared with sulphuric acid the amounts of iron dissolved are roughly proportional to the molecular equivalents, 49 parts of sulphuric acid producing the same result as 229 parts of picric acid.

"PIPE AND THE PUBLIC WELFARE."

By R. C. McWane. Published in New York by the Sterling Press. Illustrated.

Something of the ceaseless struggle of mankind, from the days when Babylon was young, 4,000 B. C., to attain a certain ideal—a pipe which will endure under ground—is interestingly set forth in this little book. The author contends that the history of pipe is the history of civilization, for upon no other single product have the great cities of the world depended in such large measure for their health and comfort, and he proceeds to show by records of actual service and various tests that cast iron pipe is, of all varieties, best fitted to safeguard the public welfare, and that it is particularly desirable for pressure conduits. Some very interesting comparisons of the performances, while subjected to hard service, of cast iron, wrought iron and steel pipe are given. The book also contains an account of the materials and methods of making metal pipe, and a comprehensive chapter dealing with the various causes for its deterioration. Altogether, because of the amount of data given, the book should be of interest, particularly to those public officials whose duty is the selection of conduits for the use of future generations.

Drugs and Medicines.

The Durpass Drug Corporation, of Manhattan, drugs, medicines, etc., has been incorporated under the laws of New York by W. F. Drennen, P. R. Gordon, and D. E. Slattery.

Newark Varnish Concern Will Add to Plant.

A contract has been awarded by the Dolph Manufacturing Corporation, varnishes, etc., for the construction of an addition to its plant, 166-170 Emmett Street, Newark, N. J. The cost of the addition will be $6,000.

THE RECOVERY OF GLYCERINE

By G. A. Moore*

Few Soap Factories Are Today Without Facilities for the Reclamation of This Important By-Product, But Although the Methods for Carrying on the Operation Have Been Greatly Improved, There Are Still Many Sources to Be Developed. In the Following Paper, the Writer Briefly Traces the Steps Through Which the Present Processes Were Reached and Points Out Difficulties Which May Yet Be Overcome.

GLYCERINE was discovered by a Swedish chemist named Scheele, in the year 1780. Sobrero prepared nitro-glycerine for the first time in 1847, and twenty years later Nobel invented dynamite.

At about this time glycerine was being utilized in other industries and the increasing consumption induced the manufacturers to recover it with more care.

The stearine candle industry was the main source of supply for many years, the glycerine being produced by the autoclave process, but the high price reached led to the investigation of other sources, particularly the waste lyes produced in the manufacture of soaps.

The presence of salts, alkali, organic impurities and coloring matter in the waste soap lye presented many difficulties and manufacturers met with varied success in their efforts to recover the glycerine. Metallic salts, such as sulphate of iron and alumina, were used in the early stages of lye treatment as coagulating and purifying agents, and many methods of more or less merit were thoroughly tried out. It was not until 1883 that the manufacturers were able to produce from the waste lyes a crude containing 80 per cent anhydrous glycerine and from 10 to 15 per cent of salt. This at once established the position of soap lye crude glycerine, and the refiners, overcoming their prejudice, no longer hesitated to work it.

Improvements in Recovery Methods.

Joseph Van Ruymbeke introduced his method of lye treatment in 1891 and his process for working still foots in 1894. William Garrigue in 1904 developed his process for the elimination of volatile fatty acids from the crude previous to distillation. Constant effort has so improved the processes that the soapmaker now has no difficulty in producing a good crude; dynamite grade can always be made in one distillation and chemically pure glycerine in two.

The improvement of the apparatus used in the recovery of glycerine kept pace with the developments in processes. Much of the early success of the manufacturers in recovering the glycerine from waste lye was due to the efforts of Scott. The first use of vacuum in distillation was made in 1882 by F. Armandy. O. Laist in 1883 applied the air condenser to glycerine stills. Van Ruymbecke in 1891 combined the use of high vacuum with heating the still by means of saturated steam and injecting saturated steam, and in 1894 applied the injection of expanded and reheated steam to stills. Garrigue in 1904 used the heat of the vapors from the still for superheating the low pressure steam injected into the still.

Characteristics of Waste Lyes.

Spent lyes as produced in the soap factories vary in quality, depending on the practice of the soapmakers. As run from the kettle the lyes consist of water holding in solution the salt added to separate the soap, some soap, free alkali in the form of caustic soda and carbonate of soda, albuminous matter in suspension as well as in solution, and the glycerine. If resin and nigre lyes are used there will be much color from the resin and nigre.

The refiner would prefer to receive the lyes free from organic impurities and coloring matter, but the object of passing water through the kettle is to remove the dirt and coloring matter from the soap as well as to obtain a good yield of glycerine. It is advisable, however, to avoid running nigre and resin lyes to the glycerine plant, but this can only be done if the glycerine has been properly removed from the soap before the addition of the resin and nigre.

The yield of glycerine obtainable depends on the amount of lye produced. In average practice the soapmaker will produce about three pounds of lye per pound of stock saponified, which lye will contain at least 90 per cent of the glycerine originally in the stock. Obviously the time to stop washing the soap is when the lye can no longer be evaporated economically.

No lye need be drawn from the kettle of such strength that the average of all the lyes will contain more than 0.4 of 1 per cent (0.4%) total alkali. All lyes will separate some soap on cooling and a storage tank should be provided in which the lyes may cool and the separated soap be skimmed off.

Neutralization of the Lye.

When the lye is ready for treatment the alkali contained is neutralized by mineral acids, and metallic salts are added for removing the organic impurities. Either hydrochloric acid or sulphuric acid may be employed, the former producing sodium chloride and the latter sodium sulphate or Glauber's salt. Glauber's salt is not so useful in graining the soap, so that eventually the salt recovered from the lye has to be wasted or the Glauber's salt separated by crystallization.

The amount of metallic salts used depends on the cleanliness of the lye. They form insoluble metallic compounds which are coagulated when the lye is brought to neutral. If sulphate of alumina is used any excess of free caustic in the lye tends to form aluminum hydrate, which will retard filtering. If the lye is left acid there is a tendency to convert aluminum soap to aluminum sulphate and set the organic matter free. In this case both would go into solution in the lye, pass through the filter and come down in the evaporator, producing a low grade crude. The sulphate of alumina would also corrode the evaporator.

---

*From the American Perfumer.

Properly treated lyes should filter readily and be water white. An excess of alkali gives the lye a yellow color and often it will not filter clear. If the lyes contain much resin lye or lye from lower grades of grease there may be an accumulation of a gummy material on the surface. This should be skimmed off as it will retard filtering and gum the press cloths.

The practice of returning silicated scrap to the kettles should be avoided, unless all the lye for the glycerine plant has been removed. Silicate of soda in the lye is not only a loss of good filler, but causes a loss in acid for neutralizing. When neutralized, silicic acid is set free in its colloidal form and any appreciable amount will retard filtering.

Concentration of Glycerine Liquors.

All lyes will contain nitrogenous matter, the amount varying with the care used in rendering the fats. This matter is not removed in the treatment, most of it appearing in the crude, increasing the figure for non-volatile residue. Lyes stored free from caustic ferment, the nitrogenous bodies decomposing forming sulphites, which give off hydrogen sulphide on acidifying, and some glycerine is converted to trimethylene glycol. Fermented lyes give considerable trouble in evaporation by foaming and the sulphides corrode the evaporator.

There are various types of evaporators for concentrating the glycerine liquors. The evaporation may be done in single or double effect, but more than two effects for spent soap-lye concentration are not practical. The type of machine selected should combine ease of operation and freedom from repairs with capacity and minimum loss by entrainment.

It is preferable to operate in two stages, that is, to evaporate the weak liquor to a half-crude containing about 4 per cent of glycerine and, when a sufficient amount of this half-crude has accumulated, complete the concentration to crude. In this way about 80 per cent of the salt recovered from the lyes is removed from the half-crude and serious trouble from salting of the heating tubes is avoided. Closed salt separators are usually provided for removing the salt during concentration.

Crude glycerine from soap lye is a saturated solution of various alkaline salts in glycerine, together with varying amounts of water, organic impurities and coloring matter. It is sold on a basis of 80 per cent glycerine content and should contain but small percentages of salts and impurities.

Obstacles to Distillation.

The presence of alkaline salts of the volatile fatty acids and organic matter retards distillation and increases the still residues. It is impossible to completely separate the glycerine from the alkaline salts of the volatile fatty acids, some of the fatty acids passing over to the distillate and some glycerine being retained in the still, the amount retained increasing in proportion to the quantity of the alkaline salts in the still. The advantage of the Garrigue process for eliminating the volatile fatty acids from the crude previous to distillation is here made apparent. There is thus in the still a very small amount of volatile acids compared with the amount of glycerine. Also, by almost eliminating the volatile acids there is produced a residue so low in volatile fatty acid salts that the glycerine retained by them is trifling.

Volatile Acids Form Esters.

It is impossible, however, to eliminate all the volatile acids in the process and any not driven off have a tendency to combine with glycerine, forming esters identical in composition with the original fat. At the high temperature of distillation any volatile acid glycerides present would decompose into fatty acids and glycerine and the volatile acids would distill over. The crude is therefore made alkaline in the still, the alkali combining with the volatile acids, holding the greater part of them in the still. The residue in the still will consist essentially of chloride or sulphate of sodium, alkaline salts of fatty acids, some coloring matter and small quantities of glycerine. If the manufacturer wishes to obtain high yields the still residues should be properly re-worked.

If dynamite grade glycerine is to be produced the distillate is concentrated to the desired gravity, bleached with a small amount of decolorizing carbon, filtered and drummed for shipment.

The Production of C. P. Glycerine.

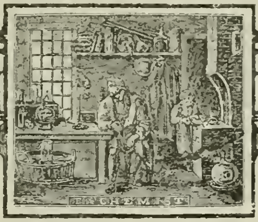
Refined glycerine must meet more stringent tests than crude, the tests for dynamite grade being determined by the powder makers. Crudes made from fermented lyes or greases which have not been washed will contain trimethylene glycol, which, if present in sufficient quantity, will make it impossible to obtain the necessary gravity for dynamite grade and the glycol would have to be distilled off.

To produce chemically pure glycerine the first distillate is bleached with carbon and redistilled. The second distillate is again concentrated, bleached and filtered. Here again the presence of glycol will be objectionable, not on account of gravity but because of the acrid taste which is a property of the glycol. It is necessary, therefore, to remove the glycol and if present in too large a quantity to be disposed of in the dynamite grade glycerine it must be sold as chemically pure glycol.

The tests given in the United States Pharmacopoeia are the ones usually applied to chemically pure glycerine. The presence of arsenic in glycerine used for medical purposes is dangerous. To prevent this, distinction should be made in the sulphuric acid used in treatments. There should be no difficulty in securing acid guaranteed free from arsenic.

CHEMICAL INVESTIGATION
EFFICIENCY & CONTROL

CONDUCTED BY CHARLES B. DAVIS, F.C.S.



BEGINNING with this issue there will be maintained through the columns of "The Chemical Engineer" a bureau of chemistry under the heading "Chemical Investigation, Efficiency and Control," the aim of which will be to assist manufacturers and dealers in effecting the economical control of their products and industrial processes at moderate fees.

The bureau, it is hoped, will be invaluable in preserving the uniformity of the products and control of the processes of those who wish to check the results of their own chemists, or who do not care to undergo the cost of the upkeep of a laboratory of their own.

The bureau will be conducted through this journal by Charles B. Davis, a well-known research chemist of wide experience in all branches of industrial chemistry, chemical and patent causes, and special machinery. From month to month Mr. Davis will answer questions relative to manufacturing processes subject to chemical control, and will undertake, at a nominal cost to readers of "The Chemical Engineer," all types of chemical investigations, with improved apparatus and the most modern methods.

The full scope of the work may be briefly indicated as follows:

Special Research of Every Description.

Analysis and Reproduction of Any Commercial Chemical Product.

Prevention of Waste and Utilization of By-Products on the Most Economical Basis.

Valuation of Raw Materials.

Food Analysis, and Disputed Points in Regard to Adulteration, Labeling, and the Enforcement of Pure Food Laws.

Bacteriological and Enzymatic Examinations, Including Fermentation Tests, Pure Yeast Cultures, Beverages of All Kinds.

Development of Chemical Inventions and Industrial Processes; Examinations and Advice on Special Machinery.

Because many manufacturers are becoming rapidly aware of the value of expert advice on matters relating to their special lines, it is believed that this method of making such advice easily and quickly available will fill a long-felt want. Questions of a minor character will be answered on this page, while major matters involving personal investigations, analyses, etc., will receive attention through the mails. All questions, materials for analysis, or letters leading to the opening of negotiations for special work will receive prompt attention if addressed to

Charles B. Davis,
care of The Chemical Engineer,
118 East 28th Street,
New York City.

I. D. C. We thank you for mentioning the fact that the working formula furnished is in successful operation and are awaiting the samples of sugar you are now forwarding. (27)

G. W. The time required for the analysis of the mixture you mention will depend entirely on what you wish determined. The samples can be shipped direct to C. B. Davis, consulting editor, The Chemical Engineer, 118 East 28th Street, New York. (36)

L. B. Coals vary in their calorific or heating value to such marked degrees that each shipment should be tested. Considerable money can be saved annually by this means. The ashes should be examined also from time to time in order to ascertain whether or not complete combustion is taking place under your boilers. Samples of at least two pounds should be forwarded for the analysis. (60)

J. K. Butters now appearing on the market are of varied composition, some of which I have found to contain as high a content of water as 35 per cent. Others are mixtures of true butter fat mixed with foreign fats. If you will forward quarter pound samples of those you want analyzed, I will be able to furnish you results in a few days after the receipt of same.

H. M. To prevent spontaneous ignition of your coal a sample should be submitted to careful analysis, as many factors depend on the prevention of this effect. The size, percentage of sulphur, conditions of atmosphere, etc., all tend to bring on this condition. (41)

F. E. B. Your waste sulphite-cellulose liquor can be rendered suitable for cattle feed by proper neutralization, concentration, and mixture with bran. A quart sample is all that will be required to be sent for this purpose. (34)

ANILINE DYES IN THE UNITED STATES

By I. F. Stone*

I. F. Stone.

Mr. Stone Believes That American Chemists and Manufacturers Are Capable of Producing Raw Materials, Intermediates and Formulae from Which Can Be Developed Colors Equal to the Best Imported Dyes, and That the End of the War Will Find Us Well Able to Supply the Domestic Demand at Reasonable Prices. Owing to the Enormously Increased Production of Raw Materials, the Present Situation May Be Regarded as Highly Satisfactory, and American Consumers Should Be Able to Obtain Everything They Need for Next Year.

IN speaking of this subject, and in order to properly compare the present situation with that of a year ago at this time, and previous to the war, I can say that just after the war, in 1914, the situation promised to be very acute, as it was evident that the shipping of colors from Europe would be stopped and there were not sufficient stocks in this country to take care of the consumers for any length of time. This proved to be very true, for as early as January, 1915, there came a great scarcity of dyestuffs and prices commenced to advance to an almost unbelievable extent. The American manufacturers were hampered in producing any additional quantities by the fact that they were buying most of their raw and intermediate materials from Europe, and with the stoppage of the shipments of colors to this country the shipping of these raw materials and intermediates also stopped. Therefore the American manufacturers were almost in as unsatisfactory condition as were the consumers, in their inability to get supplies of the raw materials.

Raw Materials at Home.

For a period, then, from the beginning of the war until about October, 1915, the situation was very acute. But in the meantime, fortunately, arrangements had been made to manufacture a number of the raw materials and intermediate products by the color manufacturers, so that by this time, viz., October, 1915, they were enabled to increase their manufacture to considerable extent. In our own factory we were particularly fortunate in this respect in that the contract for one of our principal raw materials (aniline oil) had been placed with an American manufacturer who had commenced the manufacture of this product a couple of years preceding the war, and whom it was our policy to encourage. This contract for aniline oil, together with our having our own acid plant for the manufacture of sulphuric, nitric, muriatic and other necessary acids, also together with a large stock of foreign raw materials which we always carried, enabled us not only to continue our regular production from the time the war started, but by the fall of 1915, viz., October, increased our production on many of our colors, particularly *direct black,* which was a very serviceable color for cotton and union goods and cotton and silk hosiery.

We were also fortunate enough to be able to produce at practically the same time a very satisfactory quality and quantity of *sulphur black* for cotton goods, in fact as good a quality as had been previously imported, and this, with our *direct black,* was of great service in relieving the situation on these two products. Other manufacturers also at the same time began to get into better condition to make colors, and the situation, therefore, about October, 1915, was much easier than in the beginning of the year, although the production of all these factories even then was not enough to take care of the consumption.

From that time on, however, large increases in the production of the already established factories, and the installment of a number of new factories, commenced to clear the situation so that at the present time the production of the American factories will be enough to take care of the whole consumption of aniline dyes in this country in the future, for all of what I might term staple colors, and the situation therefore at this time is very satisfactory.

All Demands Will Be Met.

In explaining the success of the American factories in reaching this position I must first explain the conditions of raw materials, coal tar, and its derivatives and intermediate materials, which they use in their manufacture. Before the war there were practically no manufacturers of what we call intermediate products in this country, the only exception being aniline oil, of which I have spoken, and this had been only made to a limited extent and not profitably, by reason of foreign competition. The basic materials, however, *benzol, naphthaline,* etc., from which practically all aniline colors are derived, were being produced in this country to quite a large extent; *benzol* for use as a solvent and for other purposes not connected with the manufacture of anilines, and *naphthaline* for a moth destroyer, but upon the demand from the aniline manufacturers for these derivatives, and for explosives and other war purposes, the American producers of benzol commenced to increase their production, and were so successful that at present there is a production of about thirty million gallons per annum, against three million gallons prior to the war. And the production of naphthaline was also largely increased, so that there is an ample supply of these products at this time, and from them are now being manufactured largely such intermediates as aniline oil, beta naphthol, alpha-naphtylamine, paranitranilin, chlorbenzol, dimethylanilin, paraphenylenediamine, etc., so that the American manufacturers of colors are able to get sufficient raw materials to manufacture enough colors to supply the whole consumption, speaking now of a general line of colors, but not of all the colors which were formerly used, there being some specialties made by the European manufacturers which we have not yet begun to manufacture, for reasons which are evident, such as not being able to secure the proper raw materials, or not being able to do everything all at once. But all of these necessary specialties will, however, undoubtedly be manufactured in the near future, so that in my opinion before another year has passed every color which is necessary to American consumers will be produced in this country.

---

*President of the National Aniline & Chemical Company, vice-president of The Schoellkopf Aniline & Chemical Works, Inc.

American Colors Hold Their Own.

There is a popular impression that American manufactured colors are not as good as those manufactured in Europe, Germany particularly, and this is an impression I wish to definitely correct, in that it is not a fact for the reason that the American colors are made from practically the same chemical formulæ as the European colors and are practically the same products in every way, the only difference being that European manufacturers, from their long experience, may get a larger yield from the same formula than the newer American manufacturers, and the American costs may therefore be more, but this does not affect the products which in my opinion are equal in every way to the products made in Europe.

For silk manufacturers, for instance, some of the same colors which they used before the war, have been available since the war—viz., Azo Yellow, Orange, Scarlet, Black, Fast Red, Bismarck Brown, Nigrosines, Indulines, Methylene Blue, Methyl Violet, etc., therefore these colors are just as good now as they ever were, and the goods dyed from them should naturally be the same as before the war. Some of the special colors, however, such as Rhodamine, Auramine, Victoria Blue, Acid Light Blue, Acid Green and Acid Violet, have not yet been manufactured for the reasons I have already mentioned, that is, lack of the necessary raw materials and lack of ability of anyone to take up everything all at once. But these colors, as I have already said, will in my opinion be manufactured before another year has passed. Some of these colors have, however, been imported from England and Switzerland, so that some of them have been available, and the fancy shades produced from them have therefore been more or less obtainable.

In addition to these aniline products for silk dyeing, such vegetable dyes as logwood, indigo, gambier, etc., have been obtainable, so that speaking generally the silk manufacturers have been able to secure practically all the staple products which they need for their purpose, and are now in a very satisfactory condition as to their dyestuff supplies.

For woolen manufacturers we are now able to supply chrome colors suitable for men's wear, sweaters, heavy woolens, etc., in black, blue, brown, green, yellow and red, which are practically equal as to fastness to any colors which have heretofore been manufactured in Europe and for ladies' dress goods, piece dye worsteds, carpets, worsted yarns, etc., we are able to furnish some acid colors in practically every shade, which are in every way equal to European colors.

For cotton goods, we are able to furnish Sulphur black, suitable for all fast work except bleaching, practically all direct colors suitable for all cotton work except a small proportion of wash fabrics such as shirtings, and basic colors such as blue, red, brown and green for printing, etc.

For leather, and other industries, we are also able to furnish practically every color which is needed.

Therefore, the whole situation is at present very satisfactory, and as I have said, every American consumer should be able to obtain practically everything he needs for next year.

"Fast" a Comparative Term.

I might say it has been particularly misunderstood by the public that American colors are not as fast as European colors were, and it seems to be the custom now for saleswomen and others in the stores, as well as the garment dyers, to specifically state that they do not guarantee colors, because they are no longer able to get the foreign colors, and I wish to say in this connection that as far as I know, no manufacturer or retailer has ever guaranteed colors even before the war, although this fact may not have been mentioned, and the only reason it is mentioned now is through a misunderstanding of the situation. Such fancy colors as ladies usually want in silk, worsteds, etc., such as pinks, light blues, light greens, heliotrope, etc., were never fast, and as far as I know, there have never been any colors which would dye them fast. In any event, the word "fast" is more or less a misnomer, as a color which is absolutely fast to everything, such as washing, fulling, light, exposure, alkalies, acids, etc., is practically unknown, so it is only comparative fastness which is meant in speaking of fast colors, and to this extent the present American colors, such as they are, are just as fast as the same colors made in Europe. There are some colors called vat colors, which are unusually fast in the above connections, but they are not manufactured in this country and have never been used to any large extent for light shades. For all ordinary fastness we are now able to furnish colors for cotton, wool and silk in blacks, blues, browns, and some other shades, so that the question of fastness is no longer a question, and it is usually only mentioned by customers who have the wrong impression of conditions.

In connection with the high prices now charged by American manufacturers of colors, many consumers are under the impression that this is because of the high cost of manufacture here as compared with Europe, but as a matter of fact, the reason is the abnormal conditions, in that the raw materials used for the manufacture of colors, like benzol, for instance, are very much higher than normally, being used for explosives and other war purposes, and this high cost of raw materials, together with the high cost of labor, under the present conditions, is what causes the high prices for American colors.

High Prices Prevail Abroad.

And by the way, these high prices also rule in Europe, as is shown by the extremely high prices asked for such colors as have been brought over from Germany by the submarine *Deutschland,* and other colors which are being imported from Switzerland, the prices on all of these imported colors being higher even in proportion than the American colors. Whenever normal conditions again prevail, and raw materials and labor are at normal costs, then the prices of American colors, as well as European colors, will resume the normal figures. In any event, American manufacturers who buy dyestuffs have no reason to complain of the high cost, because they, on their part, have in most cases advanced the cost of their products more than the proportionately higher cost of dyestuffs, for the cost of dyestuffs, as a general rule, is a very small percentage of the cost of manufactured textiles, either wool, cotton or silk, and American textile manufacturers to-day are more prosperous, as a rule, than they ever were.

In conclusion, I wish to call special attention to the three important points in my remarks:

First: That the colors made in America are fully as good in every way as those made in Germany or any other country.

Second: That we are able to furnish colors for most purposes which are fully as fast as German or other European colors, and there is therefore no reason for people not being able to get these fast colors on such materials.

Third: The definite answer, in connection with the manufacture of dyestuffs in America, is, therefore, that the present condition of the dyestuff supply is very satisfactory, and the future outlook is still more satisfactory in that we will make more colors. Everything indicates that the larger part of the business will remain in the hands of American manufacturers even after the war, instead of in the hands of the European manufacturers.

FACTORS AFFECTING THE YIELD AND QUALITY OF PEPPERMINT OIL

The effect on the yield and quality of peppermint oil of cultural and climatic conditions is discussed in professional paper No. 454, by Frank Rabak, Chemical Biologist, Bureau of Plant Industry. This bulletin, recently published by the U. S. Department of Agriculture, is based on experiments in raising and distilling peppermint plants conducted from 1908 to 1912. Conditions of soil and climate, the author finds, are influential factors in the formation of oil and its constituents in the peppermint plant. Light sand or loamy soil appeared to be most favorable for the production of an oil of high quality.

Distillation experiments were conducted with a view to determining the effect on oil yield of drying the plants previously to putting them in the stills. It was found that the yield of oil from fresh plants apparently decreases as the plant matures. Drying the plants before distillation results in a considerable loss of oil. The largest proportion of oil is found in the leaves and flowering tops. In experiments in distilling plants and parts of plants at different times of growth, the author found that the percentage of esters in the oil, which give the oil its fragrant minty odor, increases as the plants approach maturity. The menthol content of the oil bears a close relationship to the ester content. The free acidity and ester content of the oil distilled from dry plants is considerably higher than in the oil from fresh plants. The drying of the plants causes conditions favorable to making esters, while the percentage of free and total menthol in oil produced from dried plants is also uniformly high. It was found also that the formation of esters and menthol takes place most readily in the leaves and tops of the plants.

In another test it was found that the effect of shade upon the peppermint plant is to decrease the making of esters and the formation of menthol. Experiments with plants allowed to freeze indicate that frost noticeably increases esterification and the formation of menthol.

SOME NEW DYES DEVELOPED BY STUDENTS AT RENSSELAER

Achievements of students at the Rensselaer Polytechnic Institue, whose original researches in the dye field are being carried on under the direction of Professor Frederick M. Schwartz, include nineteen new dyes, numbering among them several entirely new shades.

The students have been encouraged to build up the dyes from raw materials, naphthalene, coal tar, etc. Their results include a methyl violet, a shade of lavender closely approaching indigo blue, a series of excellent browns, some yellows from derivations of picric acid, a shade of red derived from naphthol, and a fast black.

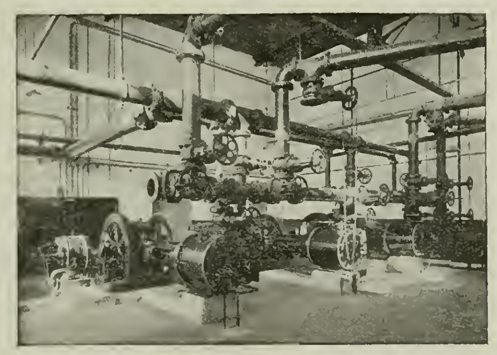
FUMIGATING BALED COTTON

Chemical Control of the Hydrocyanic Acid Gas Process

Since the Revision of the Rules and Regulations Which Govern the Importation of Cotton Lint Into the United States, Effective February 1, 1916, the Fumigation of Imported Cotton Has Become a Live Industry—Among the Companies Organized to Enter This New Field, the Vacuum Company of Massachusetts Was the First to Get Its Plants in Actual Operation, Having One Plant in Somerville, Mass., and Another in Brooklyn, N. Y.

THE object of the disinfection of cotton is to destroy the larvae of the pink boll worm, which is a native of India, the Oriental and Hawaiian Islands. The eggs which it deposits in cotton seeds hatch to life and feed on the seeds for a period as long as seven months. The present cotton disinfecting plants are built to carry out the method of disinfection prescribed by the Horticultural Board of the Department of Agriculture on March 22, 1916. This method, briefly stated, requires that the unmanufactured cotton and cotton waste must be placed in a suitable fumigating chamber where it is subjected to hydrocyanic acid gas under certain definite conditions.

In generating the gas, lumps of cyanide of sodium are placed in a steel basket in the mixing tanks and dissolved in the proper amount of water. This solution is then raised from the mixing tank to the cyanide measuring tank by vacuum. Sulphuric acid is then drawn directly from the carboys, also by vacuum, and the two liquids in the proper proportions are introduced into the generators, where their union causes the formation of hydrocyanic acid. The gas thus formed passes from the generators through cartridges of cyanide of sodium and limestone to absorb completely any free sulphuric acid. It is then drawn into the retorts. After the gas has been used in fumigation it is pumped out of the retorts and passed through a spray washing machine, where it is broken and the cyanide replaced. Two large vats, containing caustic soda solution, are used in connection with this reclamation, one being used until it has been saturated when the process is transferred to the other vat. Continuous circulation is maintained through the spray washer while pumping out the gases.



Portion of Vacuum Company's Plant at Somerville, Mass., Under Chemical Control.

To fumigate the cotton, all bales after being trucked by hand from the freight cars on the sidings to the platform cars, are moved into the retorts and the doors and gates closed. The retorts are then subjected to a vacuum of 25 inches, after which the hydrocyanic gas is introduced until the vacuum is decreased to 5 inches. This condition is maintained for one and a half hours, when the gas is again exhausted to a 25-inch vacuum; then after sufficient washing with air to eliminate any danger of escaping gas the cotton is removed from the retorts, sorted and reloaded on cars for shipment.

In operating the cylindrical retorts the platform cars are loaded alternately from either end, so that while one train of cars is being unloaded and loaded again, another loaded with cotton is in the retort being fumigated. These retorts permit a very efficient and time-saving system of handling. The entire layout of vacuum pumps and piping is such that any combination of pumps and generators may be used on any or all the retorts at one time.

The Brooklyn plant of the vacuum company is operated in the same manner as the one in Somerville, Mass. It is of smaller capacity, containing one rectangular retort 42 feet long. An additional retort and pump are, however, being installed at the present time so that the capacity of the plant will soon be doubled.

Studies, plans and specifications for both Somerville and Brooklyn plants of the vacuum company were prepared by Charles T. Main, engineer, of Boston, Mass. Herbert L. Sherman of the New England Bureau of Tests, Inc., and Arthur D. Little, Inc., acted as consulting chemists.

Bauxite from Georgia.

The Columbia Kaolin and Aluminum Company, of Washington, expects to begin shipments from its bauxite works plant at Gordon, Ga., early in April.

Central Chemical and Supply Co. Organized.

The Central Chemical and Supply Company, of St. Louis, has been incorporated by A. A. Tribble, W. P. Hovy, and John C. Meridith.

GOVERNMENT WOULD STOP FATAL OXYGEN EXPLOSIONS

Careless Methods In Manufacture of Oxygen by Electrolysis Without Frequent Analysis Blamed for Loss of Life

The attention of the Bureau of Mines, Department of the Interior, has recently been directed to a series of explosions of oxygen made by the electrolytic process in which life has been lost. The first of these explosions occurred in Cincinnati, the coroner's jury calling attention to the fact that there were no specifications for the purity of oxygen, and recommended to Col. B. W. Dunn, of the Bureau of Explosives, which bureau publishes regulations regarding the transportation of explosive substances throughout the country, suggesting that that bureau make investigations.

As the Bureau of Explosives did not have any facilities for making such tests Col. Dunn referred the inquiry to the Bureau of Mines, with the request that it investigate the question.

Presence of Hydrogen the Cause.

Active testing was begun, and the preliminary stages of the investigation have recently been completed. In the meantime, there have been many inquiries for information concerning this new danger, and the bureau has explained that it is conducting an investigation and will issue a printed report at the earliest possible moment, and is giving to inquirers certain results, or findings, which it is hoped may be of value, in a precautionary way. Answering a query recently, George S. Rice, chief mining engineer of the bureau, said:

"It is very true that there have been a large number of explosions in various parts of the country of tanks containing oxygen made by the electrolytic process due to the presence of hydrogen mixed with oxygen, and the bureau has been making an investigation of this subject on account of the extensive use of oxygen by mining companies both for welding and cutting purposes, and for use in mine rescue apparatus.

Oxygen Can Be Made Safe for Use.

"In general, the findings of the bureau are these: that strictly speaking there is no spontaneous combustion, but in all cases where sufficient data have been obtained, the oxygen has been used in conjunction with a torch for welding or cutting, and the flame has flashed back through the mixture. It is possible that ignition may occur by a jet of oxygen playing on a carbonaceous material under certain special conditions; nevertheless, these conditions are most unusual, as in many experimental tests made by the bureau the jet could not be so arranged as to cause ignition, although there was a rise of temperature at a certain point and cooling due to expansion at a point beyond."

"In all cases, however, the real danger is in the hydrogen getting into the oxygen, and it has been found that this is due to improper design in the manufacturing apparatus—i. e., the cells and electrical connections; to insufficient safeguards connected with the electric apparatus, the polarity suddently and unexpectedly shifting; to the manufacture of oxygen without frequent analyses, and to incompetent or ignorant attendants.

"Unfortunately certain makers of oxygen manufacturing apparatus have advertised that any laborer can take care of their apparatus. It is believed that the manufacture of electrolytic oxygen can be carried on in a manner to make it entirely safe. In fact, there has to be over 9 per cent. of hydrogen with the oxygen to make an explosive mixture. Nevertheless, certain tanks from one batch caused three widely separated explosions in California, killing seven men in all, and an analysis of gas from a tank filled at the same time showed that it contained over 50 per cent. of hydrogen."

CHEMISTS STOP LOSSES IN THE COAL MINING INDUSTRY

Very excellent economic reasons for the employment of a chemist in connection with the washing of coal as practiced in the coal mining industry are given by Edward H. Coxe, of Knoxville, Tenn., in a letter to the secretary of the American Institute of Mining Engineers.

"Efficient coal washing, and especially of the finer sizes," says Mr. Coxe, "can be accomplished only under the supervision of a chemist, as the proper regulation of the washer can only be had by frequent sampling and analysis of the raw and washed product and the refuse, say, at least semi-weekly: and only in this way can a check be kept on the quality of the product and the amount of good coal wasted in the refuse.

"In large operations, frequently enough coal can be saved from going to the refuse pile to more than pay the salary of the chemist."

Kalbefleisch Factory Near Completion.

Work on the construction of a large chemical plant at Chattanooga, Tenn., has been almost completed by the Kalbefleisch Corporation. The site of the factory covers thirty-two acres on "Moccasin Bend" of the Tennessee River in North Chattanooga. The corporation will manufacture paper makers' alum and sulphate of alumina at the rate of 24,000,000 pounds per annum.

Iridescent Dyes Increase Capital.

The Iridescent Dyestuff and Color Co., of Brooklyn, N. Y., has announced an increase in its capital stock from $25,000 to $50,000.

DISTILLATES

News Notes of Chemical and Allied Industries

Peru Will Import Quinine.

In preparation for a campaign against malarial conditions in that country the Peruvian Government has made arrangements to import annually such quantity of quinine as may be considered necessary. This drug will enter the country free of all customs duties and port charges and will be sold to the inhabitants by the government at cost price.

Potash Corporation Organized.

The National Potash Corporation, of Rochester, potash, chemicals, etc., has been incorporated under the laws of New York with a capital stock of $25,000 by H. N. Dons, W. A. Delongue and T. J. Morrison, Rochester.

Medical Importations.

The American Medical Import Company, of Brooklyn, has been incorporated under the laws of New York with a capital of $50,000. The incorporators are M. Gollobin, H. L. Gross and H. Ginsberg.

A Call for Cheaper Potash.

Shortage of potash at a reasonable price has caused C. Dorflinger & Sons, manufacturers of cut glass at 36 Murray Street, New York, to announce their temporary inability to make any more glass blanks for cutting until a cheaper supply is obtainable.

Dyestuff and Chemical Warehouse.

The Central Dyestuff and Chemical Company has awarded a contract for the erection, at a cost of $80,000, of a warehouse at Newark, N. J., near the New Jersey Central Railroad.

Vanillin Desired in Spain.

Pure crystallized vanillin, on which payment will be made in advance, is desired by a chocolate manufacturer in Spain, according to a press report.

New Chemical Manufacturer.

A new concern for the manufacture of chemicals, to be known as the Punch Products Company, has been incorporated under the laws of Delaware by Arthur W. Britton, Samuel B. Howard, and L. H. Gunther, New York.

Glue, Gums and Saccharine.

The Talbot Manufacturing Company, of Manhattan, glue, gums, saccharine, etc., has been incorporated under the laws of New York with a capital stock of $10,000.

$172,000,000 Invested in Dyes.

According to figures compiled by the Journal of Commerce, capital stock authorized in the incorporation of new companies for the manufacture of dyes, colors and chemicals from the first of 1915 to February, 1917, aggregated $172,289,000, while in February alone the stock of new dye and chemical concerns was $3,900,000, against $3,550,000 in the preceding month.

Soaps and Chemicals.

The Sanolene Co., Inc., of Rochester, chemicals, disinfectants, soaps, etc., has been incorporated under the laws of New York by J. A. Hotchkiss, S. D. Radcliffe and G. W. Heath, 249 Elm Street, Rochester.

William A. Flynn Moves to New York.

T. A. Flynn & Son Company, Inc., of Wilmington, Del., chemicals, tanners' supplies, etc., have announced the appointment of William A. Flynn as the New York representative of the firm.

Union Laboratory Incorporates.

Union Laboratory, Inc., of Binghamton, drugs, has been incorporated under the laws of New York by A. Packovich, H. Schrott and M. Lundin.

Salol and Salicylates.

Salol and salicylates are being made in considerable quantities at the new factories of the Russian Chemical Company, as well as naphthol, Glauber's salt and chemically pure soda and ammonia.

New Brooklyn Chemical Company.

Announcement is made of the incorporation under the laws of the State of New York of the Crossley Chemical Co., Brooklyn, with a capital stock of $40,000. The incorporators are H. B. Deyo, E. D. Loughman and C. H. Bailey.

F. C. Schapper Retires.

Following the retirement of F. C. Schapper, for thirty-two years Chicago representative of the Roessler & Hasslacher Chemical Company, Alfred C. Stepan, formerly of the New York office, has assumed sole charge of the Chicago sales office.

Potash and By-Products.

Potash and by-products will be manufactured by the Charlestown Chemical Company, of Charlestown, Tenn., which has been recently incorporated by A. L. Kirkpatrick, Melvin J. Shyer, Oscar C Schwarzenburg and others.

THE AMERICAN CHEMIST MUST ENLIST.

The tocsin has been sounded, and now as never before must the resources of America be collected and concentrated along certain definite lines which will transform their vast potentialities into tangible accomplishments. Industrial and scientific forces of a magnitude scarcely comprehended by the average individual are being set in motion to bring about a great number of widely diversified, yet correlated, results. Each of these results, in the months to come, will contribute its share toward the achievement of the common aim—complete national preparedness for aggression and defence.

The desire to do one's "bit" is universal, and for this reason the development of our national stamina and power is not a question of the existence of these forces, but rather one of their intelligent application.

Such a force is the American chemist. The importance of his part in the governmental scheme of universal service is obvious. His whole-hearted efforts are needed urgently, and he must be ready to give them without hesitation.

Thousands of men will be called upon to man our warships, and thousands more will likewise be summoned to bear our arms afield, but it is not the purpose of the government at present to utilize him in any of these ways.

The place for the American chemist just now is in a laboratory engaged in furthering the ends of the United States Government, and to this task he must give his best energies and abilities. Let no mistaken sense of duty, therefore, send him hastening to the nearest recruiting station, for such would not be the most intelligent application of the force which he represents. But by all means let him send his name at once to be enrolled among those upon whom the government can call, and then let him be ready to submit his talents and training to the direction of our leaders at a moment's notice. It is in this way, and in this way alone, that he can be sure he is serving his flag to the best of his ability.

GOVERNMENT TESTS OF GASOLINES

Physical and Chemical Properties of Many Varieties Sold Throughout the United States During 1915

By

W. F. Rittman, W. A. Jacobs and E. W. Dean.[*]

The Bureau of Mines, In the Course of Its Petroleum Investigations, Has Noted the Dearth of Published Information Regarding the Physical and Chemical Properties of Different Varieties of Gasoline Generally Marketed. Such information Is of Great Importance Both to Producers and Consumers, and for this Reason It Was Deemed Advisable to Conduct an Investigation To Determine the Properties of Gasoline Sold Throughout the United States During 1915. The Results of This Investigation Are Reported in This Paper.

Definition of Gasoline.

Gasoline has been defined in one of the standard dictionaries as "a highly volatile mixture of fluid hydrocarbons, obtained from petroleum; also by distillation of bituminous coal." The present work might well have been suggested by an attempt to make this definition more nearly complete and up-to-date. The definition is fairly adequate with regard to the source of gasoline, needing only to be extended so that it includes products extracted from natural gas by processes of compression or washing. The definition of the properties of gasoline is both comprehensive and indefinite. "Highly volatile" has no exact meaning when interpreted in degrees of temperature for boiling point or millimeters of mercury for vapor pressure. Also, the definition given does not indicate the uses of gasoline.

For the purposes of this report it is not necessary to discuss the sources and origin of gasoline, nor is there much interest at present in any use but one, which is as fuel for internal-combustion engines. The matter of chief importance is the definition of properties, which, as superficial consideration shows, introduce so many complications that a few words or even a few sentences are not adequate.

Need of Information Regarding Properties of Gasoline.

Gasoline is now of such great commercial importance that adequate information regarding its physical and chemical properties should be furnished the public. The testing of gasoline for these properties is by no means novel or original, but in the past it seems to have been limited to refinery laboratories, and the refiners have not deemed it desirable to publish the information that they possess. Detailed descriptions of the properties of products have not, apparently, appealed to them as good advertising literature. To the author's knowledge no advertisement has ever stated, for example, that a gasoline had an "iodine number" less than 6, or that 80 per cent. of the gasoline would distil between temperature limits of 50° and 125° C., nor has any attempt been made to educate the public with regard to the advantages and disadvantages of low iodine numbers and narrow ranges of volatility. The common variety of advertisement usually states that the wise user gets more power out of the brand of gasoline sold by the advertiser, or that carbon troubles are eliminated, or that "it puts life in the motor," and so on.

Automobile users sometimes try to keep a check on the number of miles their cars will run on given quantities of gasoline, and they also note relative ease of starting and freedom from carbon deposition in the cylinders of the motor. The specific gravity and odor are properties commonly considered in judging the commercial value of a gasoline and a drying test is sometimes performed to determine whether the gasoline is admixed with kerosene.

Types of Gasoline Sold in the Market.

In considering the commercial types of gasoline consideration must be given chiefly to methods of refining and production. The differences existing may be roughly divided as follows: (1) Variations due to grading according to specific gravity; (2) variations due to the source of the original crude oil, as the eastern fields, the Mid-Continent fields, and California; and (3) variations due to processes of production, as "straight" refinery products, blended casing-head gasoline, and gasoline produced by cracking processes.

Variations due to specific gravity need little discussion. It has been the accepted practice in the East for refiners to put out several grades of gasoline and naphtha, these products being differentiated according to their specific gravities. The highest-priced grade, called "76°" gasoline, is as light as is practicable to use, dangers in handling and evaporation losses being considered. Such gasoline really has a specific gravity of 73 to 74° B., the 76° figure being a trade rating which is not attained in actual practice. The other and cheaper grades of gasoline are sometimes rated according to gravity and are sometimes classed as "auto" or "motor" gasoline. Grading according to specific gravity was of some significance in the past, but now means nothing unless information is at hand regarding several other details. Of these the source of the crude oil from which the gasoline was produced is important. Gasoline from the Mid-Continent and western fields is more volatile for a given specific gravity than that produced from eastern crudes. Another factor of even greater importance than source is the method of production. Recently there has come on the market a product that is known as casing-head gasoline and is produced from certain varieties of natural gas by compression and condensation, or by washing with heavy oils and subsequently distilling the gasoline from the saturated wash oil. "Straight" casing-head gasoline is much more volatile than the ordinary refinery product and must be treated with some care both in handling and storage. It is not usually kept long in its original condition, but is generally marketed in the form of a blend with heavy naphtha or light kerosene. Such a blended gasoline may be of any gravity desired by the producer, but it is naturally different in composition and properties from the straight refinery product it may chance to resemble superficially. This is due to the fact that the blend is generally composed of hydrocarbons both lighter and heavier than those found in the "straight" refinery product.

---

[*] Extracts from a Technical Paper issued by the Bureau of Mines.

Still another possibility of variation is that due to the presence on the market of large quantities of what is termed cracked gasoline, made by the thermal decomposition, under pressure, of heavier hydrocarbons. These "cracked" gasolines always contain considerable percentages of unsaturated constituents, and may in some cases require that they be used under engine conditions different from those favorable for straight refinery products. Unsaturated compounds have certain characteristic chemical properties. Of these the ones of importance in the present connection are the powers of reaction with sulphuric acid and with iodine. The latter property, iodine absorption, is of use in the laboratory determination of degree of unsaturation.

Specific Gravity Tests.

Specific gravity measurements are made by the displacement method, an ordinary Westphal balance equipped with a special small plummet being used. This plummet proved decidedly convenient for testing quantities of liquid as small as 6 to 8 c.c. It is used with ordinary weights, according to the scheme outlined by Weiss.* Such a plummet may be constructed by anyone having elementary skill in the art of glass working. The method is as follows:

A piece of ordinary glass tubing of about 7 mm. outside diameter is sealed at one end with a short platinum wire melted into the glass where sealed. This tube is allowed to cool and about 9 to 10 grams of mercury placed in it, making a column about 35 to 40 mm. high. The tube is then cut off to within 20 mm. of the top of the mercury and sealed off with a blowpipe flame. The plummet when completed is about 55 to 60 mm. long and should have a weight of 10 to 12 grams.

Specific gravities were determined from ordinary weighings with a Westphal balance by calculation according to the formula given below.

$$\text{Specific gravity of oil} = \frac{c - a}{b - a}$$

a = the weight required to balance plummet in air.
b = the weight required to balance plummet in water.
c = the weight required to balance plummet in oil.

It may be noted that although in tabulating the results Baumé equivalents for specific gravities are recorded, the use of the Baumé scale is most heartily deplored. A full discussion of the disadvantages of this system of measuring density would be both lengthy and useless, and attention is called only to the fact that in using Baumé degrees the particular system employed should be known and stated. At least three systems are known by the authors to have more or less acceptance for liquids lighter than water. The general relation between Baumé degrees and specific gravity is expressed as follows:

$$\text{Specific gravity} = \frac{\text{Modulus}}{(\text{Modulus} - 10) + \text{degrees Baumé}}$$

The modulus 140 is approved by the Bureau of Standards and was employed in the work described herein. The modulus 141.5 is that adopted by one of the large instrument makers of this country, and is perhaps the one most largely used by oil men.

It is to be hoped that oil men will abandon this unreliable and illogical system of measuring density and resort to the more definite and simple system of specific gravity measured in decimal units. Because of the various moduli employed it is recommended that in reporting in terms of degrees Baumé care be taken to specify the particular modulus used. If the modulus is unknown, it may be of help to specify the name of the maker of the instrument used. The need of this precaution has already begun to receive recognition, and a sample of fuel oil recently sent to the bureau was accompanied by the following statement: "Baumé gravity (Tagliabue's) at 60° F., 16.2°."

Distillations.

In the distillation methods generally employed for the testing of gasoline a simple flask of the Engler type is used, and the results obtained are reasonably satisfactory for technical purposes, as all that is desired is a uniform basis of comparison for different samples. In the present experiments, however, it was thought desirable to obtain a greater degree of efficiency in fractionation, and therefore the method employed was one that a recent series of experiments* proved to be most desirable for the examination of crude petroleum.

---

*Weiss, J. M., Specific Gravity, its determination for tars, oils, and pitches. Jour. Ind. and Eng. Chem., vol. 7, Jan., 1915, pp. 21-24.

*Rittman, W. F., and Dean, E. W., The analytical distillation of petroleum: Bull. 125, Bureau of Mines, 1916, 79 pp.

The procedure employed was as follows: The distilling flask, having a bulb of 300 c.c. capacity and a column measuring 1 inch in internal diameter, 6.5 inches from bulb to outlet and 2 inches from outlet to top, was placed on a balance, and supported in an upright position by a cardboard box that contained a device for supporting the fractionating column and a quantity of aluminum beads. The flask and accessories were counterpoised and a 200-gram sample of gasoline weighed in. The supporting device was then inserted and beads enough poured in to form a compact column 5 inches high. The box, with the rest of the beads and the counterpoising weight, was set aside, so that at the end of the distillation the residue remaining in the flask could be determined.

The filled flask was then set up with an electric heater and a vertical condenser, the latter being a three-bulbed tube surrounded by a metal jacket containing cracked ice and water. The distilling flask was equipped with an accurate and sensitive thermometer. The distillates were collected in test tubes, the weights of which had been determined and marked on the glass.

The distillation was conducted at a uniform rate of about two drops a second, the tubes in which the distillates were collected being placed under the condenser in a vessel which contained cracked ice. The tubes and their contents were weighed immediately after the completion of each fraction, corked, and set aside in an ice bath for the determination of specific gravity.

After a distillation was completed the cooled flask was again placed upon the balance and the weight of the residue determined. The amount was added to the sum of the fractions and the result subtracted from the original weight of the charge, thus giving a measure of the loss incident to distillation. This procedure also furnished an excellent check upon errors of weighing and computing. If the loss was abnormally large, or if there was a gain instead of a loss, the presence of an error was immediately indicated.

The method of determining percentages by weight instead of by volume is not in common use among petroleum technologists in this country, and might be considered disadvantageous on account of the fact that commercial transactions in this country are conducted on the basis of volume. For scientific work, however, the advantage of working in terms of weight is considerable. In the first place, weight is more easily determined with proper accuracy than is volume, provided care is taken in weighing and marking tubes and equipping a balance with some convenient supporting device. In the second place, the weight of any given quantity of liquid is constant and independent of temperature, whereas the volume varies with the temperature. Finally, weighing permits easy and accurate determination of the residue left in the flask.

As specific gravity determinations were made for all the cuts, it is a simple matter to recalculate the weight percentages into terms of volume in case a need arises for such information. For the purpose of this report it has not seemed necessary to make these recalculations.

It is to be noted that the method employed does not use the conventional "end point," but employs rather the measurement of residue left after a temperature limit is reached and the quantity of distillate in the flask is relatively small. The temperature limit is, however, approximately an end point and may conveniently be considered such if a high degree of accuracy is not desired in making comparisons with the more general method.

Evaporation Losses.

Evaporation losses were determined by an empirical method which roughly paralleled conditions that cause losses in the commercial handling of petroleum products.

The procedure adopted was as follows: A 25-gram quantity of gasoline was placed in a tube made by cutting off the constricted top of an ordinary 2-ounce oil sample bottle. This open-topped tube with its contents was placed in a bath at a temperature of 20° C. and kept there for an hour. Then the tube and contents were weighed and the percentage loss calculated.

Although the results by this method are without significance on an absolute basis, in that they do not even approximately show the probable amount of loss under commercial conditions, they serve well for comparing the various samples and show the relative possibilities of loss through evaporation.

Determination of the Content of Unsaturated Hydrocarbons—Sulphonation Method.

The sulphuric acid absorption method does not give satisfactory results when applied to "straight" refinery gasolines, the general result being merely a discoloration of the acid. On this account the test was made only with such samples as had iodine numbers sufficiently high to indicate the presence of cracked products.

The procedure adopted was simple, although neither rapid nor accurate. In a 50-c.c. tube, graduated in fifths of a cubic centimeter, there were placed 20 c.c. of the gasoline and 20 c.c. of ordinary sulphuric acid having a specific gravity of 1.84, indicating a purity of 94 per cent. The two liquids were shaken together thoroughly and allowed to stand over night or until a clear-cut separation was obtained. The decrease in volume of gasoline was then read, the decrease being equivalent to the content of unsaturated compounds.

The method was undesirable in several ways, and experiments have been conducted more recently in the Bureau of Mines laboratory with a view to improving it. For the present it may be stated that the figures given in this report are of value only in showing roughly the percentage of the various products that might be removed by treatment with a sufficient quantity of sulphuric acid.

Determination of Iodine Numbers.

A particularly satisfactory and sensitive method of differentiating gasolines with regard to their content of unsaturated hydrocarbons is the determination of iodine numbers. Iodine numbers, of course, represent only approximately the theoretical iodine absorption, as they are dependent on conditions of temperature and concentration and on the nature of the reaction. It is, therefore, necessary in giving iodine numbers to specify the conditions under which they were measured. For purposes of comparison, however, the determination of iodine numbers is of great advantage. The measurements can be made with ease and accuracy, and the differences for varying saturation percentages are great because the molecular weight of iodine is high and each unsaturated bond of the hydrocarbon absorbs two atoms.

In the work described in this report Hunt's modification of the method of Hanus was used. This is described in a recent paper by Smith and Tuttle.*

A 30-minute absorption period is recommended, and the quantities of oil and iodine should be so adjusted that at the end of the reaction 70 to 90 per cent. of the iodine remains unabsorbed.

The procedure adopted may be outlined briefly as follows:

A quantity of gasoline, generally varying from 0.04 to 0.20 gram, was measured from a capillary pipette into an iodine absorption flask containing 10 c.c. of chloroform or carbon tetrachloride. Ten c.c. of Hanus solution, prepared by dissolving 13.2 grams of iodine and 3 c.c. of bromine in a liter of glacial acetic acid, was added, and the flask was stoppered and set aside in the dark for 30 minutes. At the end of this time 25 c.c. of 10 per cent. potassium iodide solution was poured in and then 100 c.c. of distilled water was added. The excess of iodine was determined by titration with sodium thiosulphate solution, prepared by dissolving about 25 grams of sodium thiosulphate to the liter and standardizing against iodine liberated by a standard potassium dichromate solution.

The iodine number is the percentage by weight of iodine absorbed. It is calculated by the following procedure: The titre of an unknown is subtracted from that of a blank (Hanus solution and chloroform or carbon tetrachloride allowed to stand 30 minutes without any gasoline), and the difference in cubic centimeters of thiosulphate solution is multiplied by the weight of iodine equivalent to each cubic centimeter of the solution. The weight of iodine thus found is divided by the weight of gasoline taken and multiplied by 100, giving the iodine number.

Determination of Calorific Value.

The calorific value of a number of the gasolines was determined with a bomb calorimeter of the Dinsmore-Atwater type. The procedure employed was the same as that normally employed for determining the calorific value of oils, except that on account of the volatile character of gasoline it was necessary to adopt special precautions in weighing out the samples. The gasoline was placed in a gelatin capsule, the calorific value of which had been previously determined, and a correction made for the quantity of gelatin burned in the determination.

Sulphur Determinations.

The sulphur content of the gasoline was determined in a number of instances by precipitating the sulphur with barium chloride from the bomb liquors and weighing the sulphate. A correction was applied for the sulphur contained in the gelatin capsules.

Engine Tests.

The engine tests run in connection with the present study were made possible through the kindness of Messrs. C. F. Kettering and J. H. Hunt, of the Dayton Engineering Laboratories Co., of Dayton, Ohio, who placed at the disposal of the Bureau of Mines their highly developed equipment, which is undoubtedly as accurate and reliable as any yet used. The results obtained show certain inaccuracies which were largely due to the inability of the Bureau of Engineers to furnish samples of gasoline large enough to permit adequately long runs and the duplication of runs. The results, however, were adequate for the purposes of this report.

Method of Conducting Tests.

Tests were made of the brake horsepower developed in an automobile engine when like amounts of gasoline were run through the carburetor. The conditions of operation were as follows:

The gasoline was tested by running an L-head, six-cylinder motor, with 3½ by 5 inch cylinder, on wide-open throttle at 1,000 revolutions per minute, the output being measured by means of a Sprague electric dynamometer.

The speed was measured by means of a Hoskins electric tachometer and did not vary over 1.5 per cent. fast or slow during any run.

The outlet water from the cylinders was kept at a temperature of 140° to 150° F. (60° to 65.5° C.) during each run, the temperature being measured by an ordinary mercury thermometer set into an oil well at the bend in the outlet line.

The carburetor was adjusted to give the best engine torque obtainable when using the ordinary grade of gasoline sold in Dayton, Ohio. The adjustment was not changed thereafter during the series of runs.

A three-way valve was connected in the line at the carburetor, and after the engine had been running on ordinary gasoline long enough to bring the water to the proper temperature, the test gasoline was turned in. After the engine had run long enough to insure that the carburetor float chamber was filled with the test fuel, a run was made on one pound of this fuel, the beginning and end of the run being indicated by an electric bell controlled by the beam scale, and the time being taken with a stop watch.

---

*Smith, W. H., and Tuttle, J. B., Iodine numbers of linseed and petroleum oils; Bureau of Standards Tech. Paper 37, 1914, pp. 1-17.

The spark position was maintained constant during the run, being placed at the point that gave the best torque with the Dayton gasoline.

The bulk of the data obtained is presented in Table 1 (on the opposite page).

Discussion of Results.

In order to discuss at length the results obtained the data for each series of analytical tests are considered under separate heads, and subheads are employed to differentiate indications obtained in regard to source or method of manufacture of products. In addition some space is given to a consideration of the relations between the properties indicated by the various series of tests.

The scheme of classification employed is shown below:

1. Discussion of individual properties.
    - (a) Specific gravity.
    - (b) Volatility or distillation range.
    - (c) Evaporation losses.
    - (d) Content of unsaturated compounds.
    - (e) Calorific value.
    - (f) Sulphur content.
    - (g) Power developed by engine tests
2. Relations between properties.
    - (a) Volatility and specific gravity.
    - (b) Volatility and evaporation losses.

Specific Gravity.

Specific gravity is the property that is almost invariably measured in the commercial grading of gasolines. Most of the samples obtained have gravities between the limits of 55° and 75° B. (specific gravities of 0.758 to 0.684). One so-called "86°" product showed an actual gravity of 80° B. (0.666). It was not, however, a common market product.

In general the eastern gasolines are lightest, their gravities ranging between 60° and 75° B. (0.737 to 0.683). Products from the Mid-Continent fields fall mostly between the limits of 59° and 68° B. (0.741 to 0.707) and those from California between 57° and 63° B. (0.749 to 0.725). Typical specific gravity values for products from the three fields are listed in Table 2. It is to be noted that there is a tendency in the eastern field to grade gasolines in three classes, in the Mid-Continent field in two classes, and in the West in one class.

Specific gravities of distillation cuts mean little or nothing in themselves and hence are discussed in connection with volatility relations. No conclusions of value may be drawn from a simple knowledge of the specific gravity of a gasoline, except that it seems that only the products from the eastern field are lighter than 70° B. Even this, however, is not a rule, but a mere statement of probability, as there would be no difficulty in making light gasolines from products from either of the other fields, and especially from the Mid-Continent field.

(a) Rated as "motor" gasoline.

Volatility or Distillation Range.

The most important property in determining the utility and commercial value of a gasoline is that of volatility, indicated in the laboratory by the distillation range. Gasoline, like all petroleum products, is a complex mixture of a number of hydrocarbons, these varying in proportion and having different boiling points. Owing to this fact, the possibility of variation in the composition of products commercially classed as gasoline is practically infinite, and all that is possible in defining properties and constituents is to indicate limiting values. Thus, for example, we may say that a high-grade "straight" refinery Pennsylvania gasoline is made up of constituents of which 10 per cent. boil below 50° C. and 85 per cent. between the limits of 50° and 125° C. A blended casing-head gasoline of apparently the same commercial grade might have 30 per cent. boiling below 50° C. and would contain a considerable proportion of constituents having boiling points ranging up to 200° C. Analyses furnishing information of this sort are useful for the study of the property of gasolines, but it should be definitely understood that they are not analyses for individual chemical compounds. Analyses for individual compounds are generally possible only through a relatively large amount of work and are of little practical value. The so-called ultimate analysis, for elements, is, of course, moderately simple, but furnishes information of small value, owing to the similarities regarding the relative proportions of hydrogen and carbon among the hydrocarbons found in petroleum.

Distillation methods necessarily involve mechanical factors which must necessarily be fixed in an empirical way. The results of a distillation are not of significance unless the method of procedure is stated. The general tendency is for apparent boiling points to be higher than actual ones, but this dis-

TABLE 1.—*Results of specific gravity tests, distillations, evaporation-loss tests, and unsaturation tests of 52 samples of gasoline collected throughout the United States in the year 1915.*

crepancy is minimized by employing a method of maximum fractionating efficiency. Such is the Hempel method, which was employed in the present work.

Classification of Gasolines.

Gasolines at present on the market may be divided into groups and classes most conveniently by the following classification:

1. "Straight" refinery gasoline:
    (a) From the eastern fields.
    (b) From the Mid-Continent fields.
    (c) From the western field.
2. Cracked gasoline (produced by cracking or synthetic processes).
3. Casing-head gasoline (produced from natural gas):
    (a) Unblended (not marketed).
    (b) Blended with various types of heavy naphtha.

Of the different types mentioned some can be detected by studying their range of volatility. Others must be differentiated by considering relations between the properties of volatility and specific gravity, and still others can be distinguished only by chemical tests.

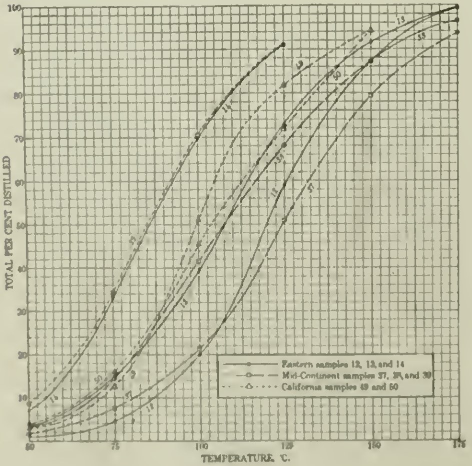
Volatility of Straight Refinery Gasolines.

EASTERN GASOLINE.

A number of different grades of gasoline on the market are produced from eastern crudes by "straight" refinery methods. These are graded according to their gravity, the rating (in Baumé degrees) generally being a little higher than the figure that is obtained in the laboratory. The lower grades are often called "motor" or "auto" gasoline.

Three typical gasolines have been selected from the series and the results of the distillations are represented by the figures for samples 12, 13, and 14, in Table 2, and by the solid curves of figure 1. These three samples were selected because they were fairly representative of the products generally sold on the market and because they were known to be produced by "straight" refinery methods from Pennsylvania crude petroleum.

Figure 1.



There are considerable differences of volatility among the different grades of products, but the boiling points are largely less than 150° C. The heavier gasolines have smaller percentages boiling below 50° C. and larger proportions distilling above 125° C. than the lighter gasolines have.

MID-CONTINENT GASOLINE.

Gasolines from the Mid-Continent fields show similar variations in volatility. Typical samples are represented by Nos. 37, 38 and 39, in Table 2, and by the broken-line curves of figure 1. The differences in the curves are similar to those in the curves representing eastern products and the degrees of difference are much the same, except that there is a tendency to include in the heavier gasolines larger percentages of higher boiling constituents.

Attention must be called to the fact that the products from the Mid-Continent fields are more heterogeneous than the eastern gasolines and that the samples selected (Nos. 37, 38 and 39, from Kansas) are chosen because they seem to be about an average. Some of the other Mid-Continent gasolines are more like the eastern, still others are more like western gasolines.

CALIFORNIA GASOLINE.

In the California market only one grade is put out by the refineries as gasoline, the heavier naphthas being sold under the trade name of "engine distillate." Samples 49 and 50 (See Table 2 and the dotted curves of figure 1) represent two California samples, one from the San Francisco district and the other from Los Angeles. The reader will note that the two samples do not show any striking or characteristic differences and also that the curves fall approximately half way between the limiting curves of the eastern and Mid-Continent series.

Figure 1 shows rather clearly that it is not possible by studying the property of volatility alone to distinguish the gasolines from the three fields. It is, however, important to note the normal ranges of volatility of gasolines produced by straight refinery methods.

Volatility of Cracked Gasoline.

It is impossible to draw any definite conclusions regarding the distillation ranges and volatility limits of cracked gasolines. A number of the samples collected show unquestionable evidence of having been produced by cracking processes, but it is also certain that they are not "straight" cracked products, but rather ones which have been blended with ordinary refinery products. No attempt has been made, therefore, to draw conclusions regarding the volatility of products of this class, except to note that the cracked gasolines on the market do not show any distinguishing features during the process of distillation.

Evaporation Losses.

The results for evaporation losses shown in column 32 of Table 1, and are entirely without significance on an absolute basis, as they show only the relative probabilities of shrinkage. The variations are proportionately great, ranging between 0.8 per cent. and 6 per cent. The average figure for the entire series is 2.13 per cent.

Content of Unsaturated Hydrocarbons.

IODINE NUMBERS.

The content of unsaturated compounds of each sample in the list shown in Table 1. was studied by the convenient and accurate iodine absorption method. The iodine numbers (To be found in Table 1, column 33) represent the percentage by weight of iodine absorbed by unsaturated hydrocarbons and show considerable variations for different gasolines. A relatively large content of unsaturated hydrocarbons indicates that the gasoline under examination is a so-called cracked product, either pure or mixed with gasoline of another variety.

The iodine numbers of the uncracked gasolines varied between 0.6 and 6.5. California gasolines showed the lowest iodine numbers, all uncracked samples from that field ranging between 0.6 and 1.5. The Mid-Continent gasolines ranged mostly between 2.0 and 4.0. The gasolines from the eastern fields showed the highest numbers, several values between the limits of 4 and 5 being discovered, and two gasolines, known to be straight refinery products in the manufacture of which no cracking process was used, iodine numbers of 5.9 and 6.5 were measured.

The iodine numbers of cracked gasolines vary between wide limits, probably on account of the fact that these cracked products are generally put on the market in the form of a blend with some gasoline that is more highly saturated. No attempt was made to determine the low limit of unsaturation which would show a product to be a blend with a cracked gasoline. It seems probable, however, that a gasoline having an iodine number of 8 or higher contains cracked products, and if the number is higher than 10 the indication is practically certain. The heavy naphthas used in producing blended casing-head gasoline are often unsaturated and in the case of several of the samples tested it is reasonable to assume that the producer may not have known that he was turning out a gasoline having a high degree of unsaturation.

The gasoline examined may be divided into three classes—(1) uncracked gasolines, (2) gasolines having small percentages of cracked products, introduced by blending, and (3) ordinary marketable cracked gasolines. In this report these classes have been differentiated as follows: Class 1, gasolines with iodine numbers of 6.5 or less; class 2, those with iodine numbers between 6.5 and 20.0, and class 3, those with iodine numbers between 20 and 60.

The character of gasolines having the iodine numbers of class 1 has been discussed. The gasolines of class 2 were apparently those in which the cracked constituents were in the minority. These products were either of the blended casing-head type or else they came from refineries putting out a moderately small proportion of cracked product. Those of the third class were the normal product of refineries specializing in the cracking process.

Sulphuric Acid Absorption.

All the gasolines of classes 2 and 3 were tested for their content of unsaturated compounds by the sulphuric acid absorption method. The percentages absorbed varied from 1 per cent. for the products of class 2 up to 3 to 6 per cent. for those of class 3.

The sulphuric acid tests were made rather roughly, and it is not assumed that the method is highly accurate. More satisfactory results could perhaps be obtained through the use of different apparatus, as mechanical shaking and centrifugal separation would undoubtedly give results more closely approximating the actual degree of unsaturation. It appears, however, that the sulphuric acid values do not follow in exactly the same order as the iodine numbers. The difference may be due to experimental error, but not necessarily, as the two methods measure different properties. Sulphuric acid absorbs each and every hydrocarbon molecule containing an unsaturated linkage. The absorption is no greater if the molecules contain two or more bonds than if they contain one. The iodine numbers indicate the number of actual unsaturated linkages.

The present work does not permit the drawing of conclusions regarding the value and utility of the cracked products. This problem will probably never be fully settled until gasolines of the cracked variety have been thoroughly tried by a large number of users and under all sorts of working conditions. However, the lack of comment from men in regard to these products seems to indicate that they are giving satisfaction. The experiments reported herein have shown chiefly that cracked gasolines are on the market and that they can be detected even in small proportion by simple and accurate chemical methods.

In this connection it may be noted that at least one other method is in use for detecting unsaturated compounds—namely, measuring under standard conditions the amount of heat resulting from the mixing of gasoline and acid.

Calorific Values.

The calorific values of typical samples, which are given in Table 3, show a difference of only about 1.5 per cent. between the highest and lowest values, and a general, though not universal, tendency for the calorific power (per unit weight) to increase as a gasoline becomes lighter.

The sulphur content of all the gasolines, as shown

Table 3.

in Table 3, is negligibly low, ranging between 0.01 and 0.05 per cent.

Power Developed by Engine Tests.

A number of engine tests of typical gasolines were made with special care and accuracy. The probable error in all the results seems to have been less than 5 per cent. and in most cases about 3. The results of the tests appear in Table 3. The amount of power developed by the different samples did not at the most differ more than 10 per cent. The average difference on either side of the mean was found by calculation to be only 2.1 per cent. From this it seems that the probable error of the experiments, although small on an absolute scale, was so large in relation to the differences that had to be measured that the limited data obtained do not permit the drawing of definite conclusions as to the chemical and physical properties that control these differences. The smallness of the variations is, however, definitely established and leads to the following important conclusion.

All gasolines can, under properly regulated engine conditions, be made to develop about the same amount of power. This result indicates that the claims made by many refiners for the superior power-producing qualities of their gasolines are largely without foundation. It does not necessarily follow that all gasolines are equally good, but it is certain that in some instances exaggerated claims are made for the number of miles obtainable from a gallon. The possible element of superiority undoubtedly lies in some products giving maximum efficiency over a wider range of engine conditions, such products consequently being more nearly "fool-proof" and "weather-proof."

The important fact is, therefore, that if the user of gasoline takes suitable care of his engine he can get almost as good results out of a cheap gasoline as out of an expensive "high-test" product. It is interesting to note that many owners of automobiles have already discovered that a "high-test" gasoline is not necessary and that they are able to get efficient service out of "home-made" blends of gasoline and kerosene. On the other hand, those who use engines not suitably constructed or find it undesirable or inconvenient to make the necessary adjustments may justly claim that high-test gasolines are worth the prices paid.

Relations Between Specific Gravity and Volatility.

As was pointed out in previous pages, certain conclusions may be drawn regarding the source, method of production, and utility of a gasoline from a study of its volatility and specific gravity. It appears that by noting the relations of these properties to each other it is possible to obtain more extensive and more important information than that obtainable by the study of individual sets of properties. One of the most characteristic differences among petroleum products from different fields of this country occurs in the relation between specific gravity and boiling point. Eastern oils are of paraffin base and for a given boiling point have a relatively low specific gravity. California oils are of asphaltic base and show a higher specific gravity for the same boiling point. The Mid-Continent oils are of mixed paraffin and asphaltic base and show specific gravities varying between those characteristic of oils from the other two fields.

In studying the results obtained from the tests of the samples collected it is necessary to be cautious in drawing conclusions as to the source of the crude petroleum used in making a gasoline from the locality in which the sample was purchased. The facilities for transporting crude oil are so highly developed that the location of a refinery means little. Some of the large companies have pipe lines extending through several states, and they are able to distribute their crude oil almost at will. In general, however, it is safe to assume that gasoline purchased in California and in parts of the Mid-Continent area near the producing fields are derived from regional crude oils. In the East, however, this does not hold, as both crude oils and refined products are largely shipped there from fields where prices are lower. A number of the samples tested were, however, obtained from refineries in the Pittsburgh district which use Pennsylvania crude oil. These products were selected as being representative of the class derived from eastern crudes.

Relation of Volatility of Gasoline to Specific Gravity of Original Sample.

Samples from the three fields may show similar distillation curves yet have specific gravities differing by several degrees Baumé. Thus, on inspecting figure 1, which shows distillation curves of a number of typical gasolines from the three fields, the reader will note that three of the gasolines (samples 51, 38, and 13), one from each field, have volatility curves that are approximately the same. The California sample is evidently a little more volatile than either of the other two. The latter are nearly equal, their curves crossing with a slight angle at about the middle point. The specific gravities were as follows: Sample, 51, from California, 0.733 (61.0° B.); sample 38, from Mid-Continent field, 0.727 (62.6° B.); sample 13, from Pennsylvania, 0.718 (65.0° B.).

Another pair of curves (for samples 39 and 12) show a Mid-Continent sample that is clearly a little more volatile than the Pennsylvania product having the adjacent curve. The gravities of these samples were as follows: Sample 39, from Mid-Continent field, 0.703 (69.2° B.); sample 12, from Pennsylvania, 0.699 (70.3° B.).

These comparisons are only qualitative, as the volatility relations could not be put on an equal basis; and in any event the data are insufficient for use in drawing exact conclusions. It is evident, however, that for gasolines of the same volatility the Mid-Continent products are heavier than the eastern and that the California products are heavier than either the Mid-Continent or eastern products.

Relations Among Specific Gravities of Distillation Cuts.

In addition to the valuable information obtainable by comparing the specific gravity of a sample with its volatility range, more or less definite conclusions can be drawn from the specific gravities of the various distillation cuts. Gravities of various cuts for representative samples from the three fields are shown in Table 4. The reader will note that the ranges of gravity of the different cuts overlap so that absolutely definite conclusions can not be drawn. There are, however, as shown by Table 4, differences for average values which fix the probable source of a gasoline. The differences are of about the same general order as those indicated for specific gravities of original samples. For a given volatility an Oklahoma sample is, in terms of gravity, about 2.5° to 3.5° B. (0.010 to 0.014 specific gravity) heavier than an eastern gasoline and a California product is from 4° to 8° B. (0.017 to 0.032) heavier than those of the East. In making this summation, consideration has not been given to cuts up to 50° C., as these have no fixed lower limit.

These differences are greater than those indicated above, and are more reliable and accurate, as they represent a large number of determinations and also fixed conditions of volatility, which could not be attained in the other case where it was necessary to depend upon the relations of single samples to illustrate the points in question.

The blended casing-head gasolines examined resembled the straight refinery products of the eastern field rather closely in volatility and specific gravity relations. The cracked gasolines resembled the Mid-Continent products, possibly on account of their being derived from crude petroleum from that field. Figures for these types of gasoline are included in Table 4.

Conclusions Regarding Volatility-Gravity Relations.

1. It seems that, by studying the volatility and specific-gravity relations of the original gasoline, or, better still, of the distillation cuts, one can determine the source of the product with a moderate degree of certainty. It is also possible, in the case of a

product made by blending samples of different volatilities and different types, to ascertain this fact by noting the gravities of the distillation cuts. The lower cuts will show the specific gravity and volatility relation characteristic of gasoline from one producing field—and the higher cuts that of gasoline from some other field. The average gravities for distillation cuts of samples from the three fields are shown in Table 4.

2. For a given volatility a Mid-Continent gasoline is 2.5° to 3.5° B. (0.010 to 0.14 specific gravity) heavier than one derived from Pennsylvania crude, and a California gasoline is 4° to 8° B. (0.017 to 0.032) heavier than the eastern products.

3. The gasolines derived from natural gas (so-called casing-head products) showed specific gravity and volatility relations similar to those of straight refinery products derived from eastern crudes. The heavy naphthas used in blending have, of course, the specific gravity characteristic of the field from which they were derived.

4. The cracked gasolines showed specific gravity and volatility relations characteristic of Mid-Continent products. The gasolines tested were derived from petroleum products from this field. It remains to be proved whether the relations of specific gravity and volatility are fixed by the cracking process or whether they remained unchanged during it.

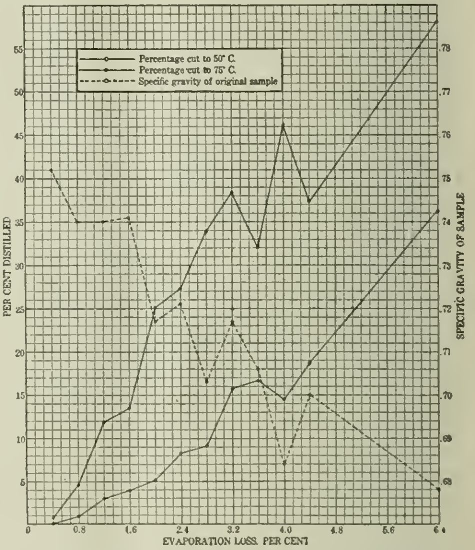
Relations Between Evaporation Losses and Volatility.

The method employed for the measurement of evaporation losses was necessarily such that the results have little value on an absolute basis. That is, it is impossible to predict from the figures obtained what the probable shrinkage will be in the commercial handling of gasoline of the types studied, even if conditions of storage, etc., are rather definitely fixed. The results do, however, show the relative probabilities of shrinkage and differentiate the gasolines in a satisfactory manner. The experimental method employed was necessarily rather crude, but it has been possible to devise a system of averaging results which show sharply defined relations.

Obviously, of course, the percentage of loss by evaporation is regulated by the volatility of the sample, which is in turn a function of its content of low-boiling constituents. The results of the experiments have established this fact in a satisfactory manner. The data obtained have been used to show the average relation between the loss by evaporation and the percentages in the samples boiling up to the limits of 50° and 75° C.

The figures for evaporation losses have been collected carefully. The nature of the figures and their small differences make evident the fact that they involve a proportionately large percentage error. It is also impossible to average these percentages for the purpose of reducing the probable error. On the other hand, however, the averaging of the values with which the percentage evaporation losses are compared seems perfectly feasible and has been adopted, yielding a relation which is fairly clear-cut and definite. Evaporation losses and average figures for specific gravity and distillation cuts up to 50° and up to 75° C. of gasolines, showing the indicated loss are shown graphically in figure 2. The curve showing the relation of the percentage losses to the magnitude of the percentage distilling up to 50° C. is consistent, though a trifle irregular. A similar curve for the total cut to 75° C. is a little less consistent and a little more irregular. A curve showing the relation between percentage evaporation loss and specific gravity of sample shows only a rough relation and is decidedly irregular. This curve clearly indicates that the influence of specific gravity on evaporation loss is accidental and exists only because in a general way light gasolines have large percentages of volatile constituents.

Figure 2.



Summary of Experimental Results.

1. Fifty-two samples of gasoline, of varieties sold throughout the United States during the year 1915, were collected and subjected to a comprehensive series of tests, and in addition about 150 samples were collected in the spring of 1916 and tested for specific gravity only.

2. Of these tests several yielded results that were more or less uniform and negative in value.

(a) The calorific value per unit of weight for the different samples showed a maximum variation of only about 1.5 per cent. between the highest and lowest value obtained. The results are accurate within about 0.2 per cent.

(b) The quantities of power developed under like engine conditions varied only about 10 per cent. between the extremes, the possible error being 3 to 5 per cent.

(c) The sulphur content of the gasolines was so small as to be negligible.

3. The volatility of the different gasolines, as indicated by the distillation range, varied widely. The normal market products have boiling ranges with lower limits varying from below 50° up to 75° C. The upper limits varied from 125° to about 175° C. There were, however, several exceptions to the above general rule. One special "86°" gasoline boiled almost entirely below 100° C. Some of the blended casing-head products contained products boiling up to 200° C. and higher.

No characteristic differences in volatility among products from the three fields were shown, except that in general eastern gasoline showed greater tendencies to vary than the Mid-Continent and the California gasolines. The volatility of the last was more nearly uniform than that of products from the other two fields. Cracked or synthetic gasolines showed no characteristic volatility properties. Blended casing-head gasolines were characterized by an abnormally large content of both low and high boiling constituents and were deficient in constituents boiling at intermediate points of the distillation range.

4. (a) Specific gravities of original samples varied over a wide range, falling between the limits of 75° and 55° B. (0.683 and 0.757 specific gravity), with one exception, the "86°" product, which is not generally sold on the market. Eastern gasolines have the largest range of gravity, varying between 75° and 60° B. (0.683 and 0.737 specific gravity), Mid-Continent products ranged between 68° and 58° B. (0.707 and 0.745) and California gasolines ranged between 63° and 55° B. (0.725 and 0.745).

(b) The specific gravities of the distillation cuts show clearly the differences in chemical nature of the hydrocarbons found in products from the three fields. For a given distillation range Mid-Continent products are in terms of specific gravity 0.010 to 0.014 (about 2.5° to 3.5° B.) heavier than eastern gasolines, and California gasolines are 0.017 to 0.032 (about 4° to 8° B.) heavier than the eastern.

5. The gasolines varied widely in their content of unsaturated compound, a high content of unsaturated hydrocarbons being characteristic of cracked or synthetic gasolines. Uncracked gasolines of the series tested had iodine numbers varying from 1 to 6.5. Products with higher iodine numbers contained greater or less percentages of cracked gasoline. The ordinary product of this type, marketed as gasoline, had iodine numbers ranging between 40 and 60. Products with numbers much lower, but still well above the 6.5 mark, may have been blends containing only small percentages of gasoline made by cracking processes.

For uncracked gasolines the percentages of the various products with numbers much lower, but still well above the 6.5 mark, absorbed by sulphuric acid, were negligible. Cracked gasolines showed losses varying from 1 to 6 per cent.

6. Relative evaporation losses seem to be approximately in direct proportion to the magnitude of the distillation cut up to 50° C.

7. By applying some or all of the tests employed it is possible to settle quite definitely the source, method of production, and probable utility of any sample of gasoline that may be examined.

Suggested Specifications for Purchase and Sale of Gasoline.

In this investigation it was not found possible to include a comprehensive series of experiments showing how the physical and chemical properties of a gasoline control its action in an automobile engine. However, certain indications obtainable from the results given are of value indicating how specifications may be drawn for the purchase and sale of gasoline. The following facts are of interest:

1. The two properties of a gasoline that tend to make its cost relatively high are (*a*) a narrow range of boiling point and (*b*) freedom from unsaturated constituents. These properties are possessed by the so-called "high test" gasolines, which have gravities of 70° to 74° B., and are obtained by "straight" distillation processes.

2. It is evident that the first factor of expense is one that can be efficiently minimized. The results of the engine tests made show that the "high test" gasolines were slightly, if at all, superior to the cheaper products as regards power development, and then only on a weight basis. As gasoline is sold by volume the actual rating runs the other way. The chief element of advantage seems to be that the "high test" gasolines yield maximum efficiency over a larger range of engine conditions. The newer designs in the way of engine construction have largely tended toward making possible the use of gasolines that are more difficult to vaporize. In any event, proper care and adjustment of an engine makes unnecessary the employment of a "high test" gasoline. It appears, therefore, that the user need not purchase the more expensive lighter grades if the engine is efficient in design and if the operator is moderately skillful and careful. Heavy gravity refinery gasolines and cracked gasolines, and blended casing-head products, are now being used in enormous quantities; and as far as can be judged from the absence of complaints regarding them, they are giving satisfactory results.

From the same indications it appears that a high degree of saturation is as unnecessary as narrow boiling range. There are on the market large quantities of cracked gasolines having iodine numbers up to 60, and the content of unsaturated compounds seems to cause the users no inconvenience. It is probable that by suitable adjustment of conditions, especially as regards setting the carburetor to produce a "lean" mixture in the engine, products of even higher degree of unsaturation may be used. The present market products are apparently so refined and blended that their characteristic properties do not even attract attention.

A minor fact that deserves mention is the undesirability of attempting to use "motor" gasoline either as a cleaning fluid or as a drying solvent. This is shown by the high boiling point of some of the constituents in many of the gasolines tested.

To summarize the matter of gasoline specifications, it may be said that the conditions under which the gasoline is to be used should be considered and then requirements should be outlined for as cheap a motor fuel as can be consumed with approximate maximum efficiency. If engine conditions are adjusted to attain this condition, a cheap gasoline will yield as much or even more power than the lighter and more expensive "high-test" products. In addition the results indicate that both cracked and blended casing-head gasolines may be utilized to as great advantage as straight refinery products.

ULTRA VIOLET LIGHT.

Its Application in Chemical Arts.

By Carleton Ellis and A. A. Wells.*

This Is the Second Installment of an Article Dealing with Investigations Conducted by the Writers Into the Possible Applications of Ultra Violet Light, and the Results Obtained Following the Exposure of Various Elements and Compounds to the Action of Its Rays. The Present Installment Continues a Discussion of the Work of Other Investigators. Part III Will Appear in the Next Issue.

PART II.

RUBBER SOLUTIONS AND VULCANIZATION.

Helbronner and *Bernstein* (The Rubber Industry, 1914, 156-63) exposed *rubber solutions,* containing different amounts of sulphur, to ultra violet rays for different time intervals, and the degree of vulcanization (or increase in viscosity) was determined by cementing two pieces of fabric together by means of the solution and determining the degree of resistance to separation. The degree of *vulcanization* (increase in combined sulphur) depends on the concentration of the sulphur in the rubber and on the thickness of the film exposed to the light. Solutions of rubber vulcanized with ultra violet rays are permanent, and if the operation is carried out in the proper manner, will remain constant for a long time. Besides rubberizing cloth the solutions can be used for cements (joining and rubberizing leather and repairing rubber goods). By using these solutions for joining two pieces of rubber a positive absorption of the solution is stated to be obtained and the two pieces of rubber are not separated by a layer of rubber, as is the case where ordinary cements are used.

A thin layer of the rubber solution on an endless band was carried beneath a cylindrical quartz mercury vapor lamp, provided with a cooling jacket, and the vulcanized solution removed by a scraper. The strength of the rubber when used as a cement was determined by measuring the load required to separate two layers of canvas united by means of the vulcanized solution. The strength and viscosity of the rubber solutions before exposure to the rays varied inversely as the percentage of sulphur employed. The amount of combined sulphur in the vulcanized solutions varied very little for concentrations of rubber up to 6%, but fell very rapidly above that point (the added sulphur being kept constant at 5% on the solution). The amount of combined sulphur and the strength of the vulcanized solutions increased with the amount of sulphur used up to 6-7% and then diminished. The thickness of the layer of solution employed was varied according to the color of the rubber and it was found advisable to allow a margin of 40% above the thickness indicated by the spectroscope for complete absorption of the rays. Curves are reproduced showing the depolymerizing effect of the ultra violet rays on a solution of unworked Ceylon rubbers, which showed complete depolymerization (as measured by cementing strength) in seven seconds, and on the other hand the repolymerization of solutions of well worked rubber containing sulphur, the strength in this case, after 54 seconds exposure, almost reaching that of the original unworked, unexposed rubber. The vulcanized solutions were permanent, but tended to undergo further vulcanization after removal from the direct influence of the rays.

Helbronner and Bernstein (Caoutchouc et Guttapercha, 1915, 12, 8720, 8721; J. S. C. I., 1915, 1105) state that rubber in solutions containing sulphur becomes vulcanized on exposure to ultra violet rays, but the vulcanized rubber forms a stable gel and is not precipitated even after several months or by heating to 80°C. for 18 hours; on evaporation the solution yields a film which is insoluble in rubber solvents. Rubber, vulcanized by ultra violet light only, contained 0.6% of combined sulphur, and Helbronner and Bernstein consider that the sulphur acts as a polymerizing agent, and that the combination of rubber with sulphur during vulcanization is merely a secondary reaction. Small quantities of sulphur (0.2%) exert a similar polymerizing action in the synthesis of caoutchouc from isoprene, rendering the product insoluble in benzene.

---

*All rights of publication in book form reserved by the authors. Consulting Chemists and Chemical Engineers, 92-98 Greenwood Ave., Montclair, N. J.

Bernstein (British Patent 17,195, July 26, 1913) proposes vulcanizing India rubber solutions containing sulphur by exposing them to the action of ultra violet rays produced either by a quartz mercury vapor lamp or otherwise. The solution may be spread on a moving metallic ribbon. A solution of rubber in benzene containing 6% of rubber and sulphur equal to 10% of the rubber when exposed in a film 0.5 mm. thick requires 40-50 seconds for vulcanization. Ordinary or high temperatures, pressure or vacuum, air or netural gas atmosphere, may be used. During his experiments with different kinds of rubber Bernstein (J. Franklin Inst., 1913, 345; J. Chem. Ind., Vol. XII, 193,273) showed that the viscosity is diminished by heating, by mechanical working and by exposure to ultra violet rays, and that if the depolymerization indicated by this reduced viscosity be carried to completion the final result is the same, whatever the agency employed—i. e., solutions of the depolymerized rubber of the same concentration show the same constant viscosity. With Frank and Marckwald's viscosimeter and using a three per cent solution of rubber in xylene the final constant viscosity value is 15 seconds. Depolymerization on heating takes place most rapidly between 60° and 85°C., according to the kind of rubber, and these temperature limits are close to the temperature above which, according to Spence, vulcanization occurs most actively. The vulcanization of rubber can be produced by exposing a xylene solution of rubber and sulphur to ultra violet rays. A xylene solution of a mixture of Hevea plantation rubber with 6% of sulphur was allowed to evaporate so as to leave a thin film on a transparent quartz plate. This was covered by another quartz plate and exposed on both sides for 40 minutes at a distance of 15 cm. to the rays from a Heraeus lamp of 3 amperes and 110 volts. The film then possessed the properties of vulcanized rubber and contained 2.56% of combined sulphur. Other experiments showed that the percentage of combined sulphur increased with the duration of exposure to the rays. The deterioration of vulcanized rubber on exposure to ultra violet rays, observed by Henri, is considered to be chiefly due to "after-vulcanization." The effect of heat or exposure to ultra violet rays on sulphur alone or in solution is to polymerize it, converting it into a colloidal, insoluble form. Bernstein agrees with Axelrod that the vulcanization of rubber involves a depolymerization of the rubber, followed by a polymerization of the mixture. If this polymerization of the mixture be of a physical character it must be accepted that it is due to the adsorption by the depolymerized rubber of the polymerized insoluble sulphur, and this would explain the difficulty of extracting the so-called combined sulphur. It is however, not yet possible to decide finally between the chemical and physical (adsorption) theoris of vulcanization.

Stern (Chem. Zeit., Rep. 1913), in discussing the work of Bernstein, states that depolymerization occurs together with vulcanization.

From Bernstein's observation that normal vulcanization of *caoutchouc* proceeds at ordinary temperatures under the action of ultra violet light, it is concluded by *Ostromyslenski* (J. Russ. Phys. Chem. Soc., 1915, 47, 1892-1898; J. S. C. I., 1916, 370) that, in absence of air, this light activates sulphur by converting it into thiozone; the vulcanization is then effected partly by the latter and partly by the ozones formed simultaneously.

According to *Schopper* (Gummi-Zeit., 1915, 29, 1250; Z. Angew. Chem., 1915, 28, Ref., 644; J. S. C. I., 1916, 356) solutions of *coumarin* derivatives—e. g., 1% solution of dimethylamino-methylcoumarin—may be used to absorb the ultra violet rays and hence protect the fabric of balloons from damage by sunlight.

HALOGEN COMPOUNDS AND HALOGENATION.

The effect of ultra violet rays under varying conditions in the chlorination of *toluol* at 150°C. has been studied with the following results:

(a) Ultra violet light and its visible light gives high yield.
(b) Darkness gives medium yield.
(c) Visible light from ultra violet lamp gives low yield.

Hence, if the determinations are correct or results uninfluenced by any other factor, *visible light retards chlorination, ultra violet light greatly accelerates it* and the latter plus the accompanying sensible light gives a lower chlorination rate than the ultra violet rays alone. Accordingly a screen which stops the passage of sensible or visible light and allows the passage of ultra violet rays would enable the full chlorination rate to be obtained. Glass which has been coated with a thin film of silver stops visible light but not ultra violet light, and its effect should be tested in this connection.

In experiments on the photobromination of *toluene*, made in an atmosphere of 96% oxygen and 4% nitrogen, *Le Blanc* and *Aldrich* (Zeit. Elektro-Chem., 20, 543-7, 1914) found that the yield of benzyl bromide was independent of the intensity of light and was constant throughout the entire portion of the spectrum investigated. The speed of the reaction decreases with decrease of wave length and is practically zero for wave lengths shorter than 300. Experiments on bromine in carbon tetrachloride and in hexane indicate that the increased reactivity of bromine in the light is not due to the splitting off of electrons.

Baskerville and *Riederer* (J. Ind. Eng. Chem., 1913, 5) have investigated the action of ultra violet light on the reaction between natural gas and chlorine and have found that chlorination was not materially accelerated by ultra violet light, but that an acceleration was noted when using the rays of the visible blue spectrum.

Matthews, Bliss and *Elder* (British Patent 16,828, July 22, 1913) have found that in the production of organic compounds halogen hydride is removed from halogen containing compounds with the exception of mono and dihalogen hydrocarbons by treating them in the form of vapor with steam at a suitably high temperature. The mixed vapors may also be treated with the silent electric discharge or subjected to the action of ultra violet light. The removal of halogen hydride may be accompanied by the removal of carbon dioxide, water, ammonia, etc. These subsidiary reactions may be effected or facilitated by means of catalysts or suitable reagents. For example, styrolene is prepared from B-bromo-hydrocinnamic acid.

In a process of the *Badische Company* (German Patent 266,119, Oct. 31, 1911) for the production of *iodine derivatives* of the paraffine series (excepting methane) in vapor form by mixing the hydrocarbons in the dark with the hydriodic acid and subjecting the product to the action of chemical light rays or silent electric discharges the reaction temperature may be reduced by operating under diminished pressure.

Coehn (Berichte, 42, 3183) has found that *hydrochloric acid* is dissociated by the action of ultra violet light. Pure, dry hydrochloric acid gas was placed in a quartz vessel and exposed to light from a quartz lamp, and by such exposure at a relatively low temperature a considerable degree of dissociation occurred. Measurements indicate that this was approximately as great as that obtained when hydrochloric acid is subjected to a temperature of 1500°C. Under the influence of the silent electric discharge dissociation also takes place. Light rays passing through ordinary glass do not affect the equilibrium, but merely the velocity of reaction between chlorine and hydrogen (Abegg and Auerbach, Hdb. d. Anorg. Chem., Vol. IV, part 2, 112).

Marmier (Comptes. rend., 1912, 154, 32) has decomposed solutions of *sodium thiosulphate* containing less than 6 grams per litre by ultra violet light, sulphur and hydrosulphite being formed; the latter is itself rapidly decomposed by the ultra violet light and after 75 minutes exposure no traces remain. The liquid then contains chiefly sulphite. With concentrations above 5 grams per litre no hydrosulphite could be detected.

McLennan (Proc. Roy. Soc. London (A), 91, 23-9, 1914) carried on some experiments using a highly exhausted tube of fused quartz containing a few crystals of *iodine*. This was inserted axially in a Cooper-Hewitt mercury arc lamp with a lateral anode and a short extension at the positive end to which the quartz tube was sealed with wax. The iodine vapor tube was provided with a window of clear quartz toward which the collimator of a quartz spectrograph was directed. Iodine vapor can be stimulated to the emission of a fluorescence spectrum excited by ultra violet light from room temperature to at least 1000°. The wave lengths which can stimulate the fluorescence of iodine vapor lie between 2,100 and a lower limit, probably about 1,800A. Resonance spectra cannot be obtained with iodine vapor when illuminated with light from the mercury arc of wave length shorter than 5,460.74. Portions of the ultra violet fluorescence spectrum of iodine vapor were obtained with methyl iodide and mercury iodide at a temperature of about 326°. Mercury iodide and potassium iodide at a temperature above 326° exhibit fluorescence spectra of their own when excited by light from the mercury arc.

IODIDES.

Strontium iodide in neutral aqueous solutions decomposes, according to Kailan (Chem. Abstracts, 1914, 14) the most rapidly, while *barium iodide* seems to decompose faster than *potassium* and *magnesium iodide,* but when exposed to ultra violet light barium iodide and strontium iodide decompose faster than potassium iodide and sodium iodide, but the barium iodide decomposes faster than the strontium iodide. At 8 cm. from a quartz mercury lamp the decomposition is 200 to 800 times as fast as under the influence of the rays from radium preparations containing 80 to 200 milligrams of radium. The nature of the decomposition caused by penetrating raidum rays and by ultra violet rays is much the same, but the extent of the decomposition is often different. Iodide solutions containing about 1/800 molecule per litre of hydrochloric acid were decomposed more rapidly than in neutral solutions.

ALIPHATIC ACIDS.

Kailan (Monatsh. Chem., 1913, 34, 1209-1244) has found that when dilute (0.5 to 2N-) solutions of *acetic, oxalic, malonic, succinic, malic* and *tartaric acid* are exposed in quartz cells to the action of a quartz mercury lamp, slight decomposition takes place. The speed of decomposition of a dibasic acid was increased by the introduction of an alcoholic hydroxyl group into the molecules. No decomposition took place under similar conditions in glass vessels. The speed of decomposition increases with length of exposure, but does not increase in proportion to increasing concentration of the acid. Any dissolved oxygen only plays a subordinate part, since the acid solution showed at most only a slight reduction in the speed of decomposition when all air had been expelled.

OXIDATION OF SULPHUR DIOXIDE.

Coehn and *Becker* (Z. Physik. Chem., 1910, 70, 88,-115) have studied the formation of *sulphur trioxide* from *sulphur dioxide* and oxygen under the influence of the radiation from a quartz mercury lamp. Experiments made with a quartz reaction vessel mounted within a mercury lamp showed that the formation of sulphur trioxide proceeds fairly rapidly even at the ordinary temperature and more rapidly at higher temperatures. The equilibrium is quite distinct from that attained in daylight. With a mixture of one part sulphur dioxide to one of oxygen equilibrium is attained with a production of 65% of sulphur trioxide. This equilibrium can also be attained starting from sulphur trioxide. At 160°C. with the gases confined in the reaction chamber equilibrium was attained in one hour. In daylight at temperatures below 450°C. the equilibrium condition corresponds to practically 100% of sulphur trioxide. Again the light equilibrium (attained on exposure to the radiation from the mercury lamp) is not displaced by rise of temperature up to 800°C., whereas the dark equilibrium is displaced considerably by rise of temperature above 450°C. With a mixture in the proportions of one part of sulphur dioxide to thirteen parts of oxygen, at 800°C., the yield of sulphur trioxide is 80% on exposure to the rays from the mercury lamp, whereas in daylight, the yield is 44% of sulphur trioxide. The temperature coefficient of the velocity of the photochemical reaction was found to be 1.2. Coehn and Becker consider that a technical photochemical process for the production of sulphuric acid is quite feasible, since on using air in place of oxygen no oxides of nitrogen are formed. Some experiments were made with a special mercury lamp composed essentially of a quartz tube, 115 cm. long and 1.8 cm. diameter. This was inclosed in a tube of opaque English quartz, 100 cm. long and 5 cm. diameter, the annular space between the two serving as reaction chamber. At 450°C., and with the gaseous mixture passing at the rate of 100-150 c. c. per minute, yields of 67.4, 70.8, 92 and 90% respectively of sulphur trioxide were obtained, with 0.78, 0.66, 8.7 and 9.3 molecules of oxygen per molecule of sulphur dioxide.

Sulphuric acid may also be prepared (German Patent 217,772, July 9, 1907) by exposing a mixture of sulphur dioxide and oxygen (or air), preferably containing excess of oxygen, to ultra violet light of low intensity, the gases being heated above 300°C. The yield of sulphur trioxide is increased if the reaction mixture after exposure to the rays be cooled in stages.

MISCELLANEOUS CHEMICAL REACTIONS.

Thiele (Z. Angew. Chem., 1909, 22, 2472) has studied the influence of ultra violet light from a high tension Haraeus mercury lamp on different chemical reactions. The quartz reaction vessel was placed opposite the middle of the lamp only a short distance away and was cooled by a water spray which formed a thin mantle around the vessel. The E. M. F. supplied to the mercury lamp was maintained at about 120 volts. Experiments with mixtures of hydrogen and oxygen were conducted with moist gases, with gases dried by means of sulphuric acid, and with gases dried by contact for eighteen days with phosphorus pentoxide. Combination between the two gases was accelerated by ultra violet light and the presence of moisture was not essential, the reaction velocity being indeed somewhat greater with the dry than with the moist gases. *Carbon monoxide* and *oxygen* also combine when exposed to ultra violet light, but less readily than hydrogen and oxygen. In ultra violet light interaction takes place in a mixture of *hydrochloric acid* and *air,* even when the gases are dried by means of sulphuric acid. *Hydrobromic acid* is also decomposed by air in ultra violet light. The formation of *hydrogen peroxide* from water and oxygen in ultra violet light could be observed only occasionally and appeared to depend largely upon the experimental conditions, possibly upon the presence of impurities. On the other hand, the decomposition of hydrogen peroxide and of *potassium percarbonate* and *ammonium persulphate* was considerably accelerated. *Formic acid, ammonium oxalate, peptone,* and *egg albumen* all suffered more or less decomposition on exposure to ultra violet light. *Potassium nitrate* was reduced to nitrite, with liberation of oxygen; in a N/10 solution, 6.3 per cent of the nitrate was reduced in 2½ hours. A small piece of filter paper lost 0.8 milligrams in weight when exposed for three hours to the ultra violet light. Experiments were also made with water containing about one per cent. of *sulphur* in suspension. In the dark there was no measurable change, after exposure to sunlight for three days, a current of air being passed through the water, a quantity of acid equivalent to 0.5 milligrams of *sulphuric anhydride* was found, after three hours exposure to the ultra violet light (at a distance of about 8mm. from the lamp), quantities of acid equivalent to from 34.6 to 44.8 milligrams of sulphuric anhydride were found.

Condensation of Organic Compounds.

De Wierusz-Kowalski (French Patent 466,918, Dec. 8, 1913) in a process of effecting chemical reactions by means of ultra violet rays, brings about the condensation of organic compounds, such as a mixture of *acetone* and *methyl alcohol* by conducting the mixed vapors under reduced pressure through hollow bodies which are in a high frequency field, in such manner that these vapors themselves act as carriers for the luminescence.

Lesure (J. pharm. chim., 7, 1, 569-75, Chem. Abs. 1911-963) studied the penetration and chemical effects of a Cooper-Hewitt lamp of 3 amperes and 100 volts on solutions of 24 substances. In most of the solutions examined the penetration was as great as with water alone, but only 0.2 to 0.1 as great as in the case of solutions of atoxyl, caffeine, salicylate of eserine, apomorphine, hydrochloride, gentiopicrin and for olive oil, and almost nil for mercury iodide, the bichloride and bisulphate of quinine and for iron methylarsinate. Solutions of *silver nitrate, eserine salicylate, apomorphine hydrochloride, arbutin,* and *guaiacol* were only slightly discolored, but without polarimetric change after an exposure of 15-30 minutes; while solutions of *cocaine hydrochloride, mercury* *benzoate* and *bichloride, sodium cacodylate, calcium glycerophosphate, quinine bichloride* (1%), *pilocarpine hydrochloride* and the artificial *serums* were not affected upon exposure to the light for 30 minutes. Olive oil was bleached in less than half an hour, but not noticeably changed otherwise. To ascertain the possibility of applying this light in sterilizing substances easily decomposed by heat in sealed tubes, cultures of *baccilus coli* were added to 1% solutions of aucubin (permeable) and of gentiopicrin (slightly permeable) and these exposed for 30-1,800 seconds to the light. Sterilization was complete only in the first case.

Baskerville (Electrochem. and Met. Industry Nov. 1906, 435) discussing the use of ultra violet light in the laboratory and in practice, observes that the one very marked property of ultra violet is its power to transform *oxygen* into *ozone*. This takes place best at low temperatures. It has been thought that the ultra violet light from the sun forms ozone in the upper atmosphere which then settles down and oxidizes the impurities nearer the earth. An electroscope is almost instantly discharged under the influence of ultra violet light, but the action is quite slow if a quartz screen is interposed. He notes that an important application of ultra violet light has been in the testing of minerals. Certain minerals are inert, others fluorescent, some phosphoresce, and still others are both fluorescent and phosphorescent. Kunzite was discovered by aid of ultra violet light. A large number of spodumane samples were tested and all found to be inert except one. Upon closer examination this one was found to contain a hitherto unknown mineral which was named *Kunzite* in honor of the discoverer, Dr. Geo. F. Kunz. All the minerals from Mono Lake are phosphorescent after treatment with ultra violet light. Some of the same minerals from other localities are not phosphorescent. The genuineness of *diamonds* may be proven by their phosphorescence after being subjected to ultra violet light. The purity of tailings or precipitates may be tested and minerals sorted. A crushed mineral may readily be separated into a fluorescent and a non-fluorescent portion by sorting while acted upon by ultra violet light. This principle is made use of by the New Jersey Zinc Co. for testing *willemite* concentrates and tailings. The willemite is fluorescent while the gangue is inert. If the tailings contain no fluorescent specks it shows that the concentrating tables are working well. The eye can also roughly judge the degree of concentration in the concentrates.

Wolff (Chem. Zeit., 1912, 36, 197) has examined certain samples of calcined (dehydrated) *potassium carbonate* by means of ultra violet rays which showed in places, a livid red luminescence. With the carefully purified salt this effect was not observed. The effect was traced to the presence of potassium sulphide. Exposure to ultra violet rays affords a simple means of detecting even traces of this substance in commercial potassium carbonate. The salt must be dehydrated and cooled before examination.

Mathews and *Dewey* (Eight Int. Cong. Appl. Chem., 1912, Sect. IX. Orig. Comm. 20,247) have studied the action of ultra violet light on solutions of *sodium sulphite, potassium permanganate, potassium bichromate* and *oxalic acid*. It was found that sodium sulphite solutions are not oxidized by ultra violet light in absence of air, but that the oxidation in presence of air is greatly accelerated by such light. Potassium permanganate and potassium bichromate are very stable towards ultra violet light. Solutions of oxalic acid are decomposed very slowly by ultra violet light, but the reaction is much accelerated by the addition of uranium salts; in this case the decomposition proceeds regularly, the rate varying directly with the amount of uranium salt present.

ACTION ON GLYCERINE.

Henri and *Ranc* (Comptes, rend., 1912, 154, 1261) by subjecting a 10% aqueous solution of *glycerine* for six hours to the action of ultra violet radiation from a 500-volt quartz mercury lamp, have shown that the glycerol molecule is decomposed with the production of formaldehyde and acids as well as other aldehydic substances. The decomposition is considerably increased by the presence of hydrogen peroxide, the activation being proportional to the quantity of peroxide added.

Bierry, Henri and *Ranc* (Comptes, rend., 1911, 152, 535) carried out experiments on the action of ultra violet light on glycerol. Two mercury lamps in parallel served as the source of light. The liquids were placed in quartz flasks or in large open porcelain basins. The experiments were made at different temperatures, in presence of air or in vacuum, and with or without shaking. Lastly the concentration of the glycerol solution was varied from 1 to 100%. After treatment the solutions were concentrated in a vacuum and their behavior studied towards Fehling's solution and phenylhydrazine. The action on neutral glycerol at 25°C. in the presence of air leads to the formation of a glycerose giving a positive phloroglucinol reaction for glyceric aldehyde. The quantity is small and other substances reacting with phenylhydrazine are also formed. In the presence of alkali the product is not glycerose but B-acrose which was identified by means of the phenylosazone. The amount formed is small, but it may be increased by the addition of salts of iron or cobalt or in particular by uranium salts. Numerous other compounds are also formed.

(To be continued in the May issue.)

MARKET DESIRED FOR RAW AND TANNED HIDES.

An American consular officer in Spain has transmitted the name of an exporter of kidskins for the manufacture of gloves, fancy leather for shoes, raw sheepskins and goatskins, and dressed sheepskins for use in fancy goods, who desires to get in touch with American importers of these goods. Correspondence can be in Spanish or English. The name of the exporter can be obtained at the Bureau of Foreign and Domestic Commerce or its district or co-operative offices by referring to file No. 84721.

THE COMMERCIAL DEVELOPMENT OF TECHNICAL BUSINESSES.

George H. Gibson.

By George H. Gibson*

The Translation of Technical Values Into Business Terms in Such a Manner as to Forcibly Register Their Practical Advantages in the Minds of Technically Trained Consumers Is of Extreme Importance, Declares the Writer, and Many Sound Inventions Have Gone Begging Through Lack of Ability to Do This Effectively. In This Discussion of the Subject, the Essential Elements of an Ideal Technical Business Are Set Forth, and the Advantages Accruing From the Right Kind of Publicity Emphasized.

THE application of science proceeds at an accelerated pace. The days have about gone by when one good idea would keep a family in business for several generations. No one dare rest content, for as Solomon remarks, "Yet a little sleep, a little slumber, a little folding of the hands to sleep, so shall thy poverty come." Every manufacturer, and particularly manufacturers of engineering appliances and products, must maintain a constant output of improvements and new developments in order to protect his investment in plant, organization, and good will, and indeed, to stay in business. As has justly been said, the invention of a new machine or process—by some one else—may be as disastrous as a fire, and far more likely to occur.

Moreover, the more progressive, the more advanced, a concern is, the greater will be its volume of new developments and improvements. Inventions breed inventions.

Speedy Marketing Saves Money.

At the same time, the investment of time and money in research and development is a capital risk, that is, the preliminary investigation upon which the design of improved apparatus is based and the provision of manufacturing equipment and organization for turning it out must largely be paid for before the market for it can be developed. It is only by the prompt enlightenment of the prospective consumer, in other words, by educational advertising regarding the applications and advantages of the new article, that the loss of time and the waste which always intervene between the perfection of a device or process and its general use, can be reduced.

The introduction of new things is a speculative venture which bars the timid—but for that very reason it is highly profitable. Patents more or less effectively insure to the originator a safety zone, protecting him from competition for a limited period that he may have the opportunity to recover his great initial outlay. Advertising, however, is equally useful, since it can shorten the period of loss, conserving for profit-making a greater portion of the 17 years' monopoly conferred by the patent and increasing the volume of profit. Advertising itself exerts an accelerating influence on technical development, for before advertising, one should have something worth advertising. Much of the strategy in the competitive selling of engineering appliances consists in originating better methods or designs, or new and improved products.

Foresight Plus Convincing Arguments.

Good business has been defined as the art of selecting probabilities, and it is certainly true that the greatest successes in the engineering businesses have come to men who had the ability to do the following things:

(1) Foresee the need or opportunity,

(2) Develop the solution, and

(3) Focus the attention of the public upon the problem and its solution.

As examples, I might mention Edison with the incandescent lamp, Westinghouse with the air brake and alternating current transmission, Hunt with rope transmission, Sturtevant with fans and blowers, De Laval and Parsons with the steam turbine, Babcock and Neier with the water-tube boiler, Diesel with the oil engine, the Wheelers with surface condensers, Hill with technical journalism, Thurston with technical schools, Patterson with the cash register, Herschel with water meters, Kent with his handbook, and many others.

Early Struggles of Corliss.

The inertia and prejudice which must be overcome in the introduction of a new device may be illustrated by the experience of Corliss with his variable cut-off four-valve steam engine. After he had perfected and demonstrated the remarkable savings of his engine as compared with the engines then common in this country, he was still compelled to give the engines away and take his payment in the fuel saved during the first year's operation, in order to make headway.

---

*Tribune Building, New York City.
From an address delivered before the Technical Publicity Association, March 8, 1917.

Many people have the idea that the invention is the important thing. Very few engineering businesses, however, are founded altogether on exclusive and basic patents. They are based rather on a combination of scientific knowledge and business sagacity, with the help of such protection, monopoly or trading advantage as can be obtained from the detail patents which it may be possible to secure as the development of the art unfolds itself. A man may have the germ of a good idea for a successful business, but still nothing that can be protected by a patent, even though patentable improvements will doubtless be discovered upon developing the idea. Nevertheless, the essential factor is the broad judgment or foresight which leads him to take up certain matters at a particular juncture, and not the specific mechanical contrivances by which he may carry out his ideas. In such cases, the best protection for the idea is advertising by means of which he can promptly get the full benefit of the potential demand for his product before competitors have had time to imitate and develop. Once he has his organization and business well under way, competition will be at a disadvantage.

Organization of a Technical Business.

For businesses up to a certain size, there is nothing that will beat one-man efficiency. The man who can see a need or an opportunity for a need and act accordingly is fit to be the head of a business, if he is also an administrator. However, the organization of modern industrial enterprises branches out into a great multiplicity of specialized details and we cannot always get in one man all those qualities of genius that are necessary in the inventor, in the captain of industry and in the promotion expert. We therefore have performing these functions a number of men who may be described as follows:

First, there is the general strategist, who may have the title of president, general manager, chief engineer, and not infrequently sales manager, since the study of how to sell a product as already built leads almost invariably to the discovery of improvements whereby it can more easily be sold in larger volume and at a greater profit. It is his disposition and function never to be satisfied with things as they are. He is continually studying the trend of engineering, scientific and business developments with a view to visualizing their probable future course. His policy is to build a monopoly of information and brains and then to serve the public with little or no competition by having the best solution for each new problem as it arises.

Nicholson: Chemist and Business Man.

A good example of the necessity of appreciating research on the part of the directors of industrial enterprises is supplied by the editor of London "Engineering," who relates that the firm of Simpson, Maule & Nicholson, in their day leading manufacturing chemists in England, became millionaires largely through the fact that Nicholson was a very able chemist. When he retired, the firm ceased to develop. His successors employed several very able chemists, but these had no control over the business policy and the end was disaster. At one time their leading chemist was the late Prof. Meldola. When he invented his blue, however, the firm refused to take it up, and he accordingly published an account of his discovery, with the result that it founded the fortune of a leading German firm. The successor of Meldola was Prof. Green, who invented primulin, a dye of an entirely new type. This the firm refused to patent, and within a few weeks it was in consequence made in Germany, the whole advantage being lost to England.

Again, some 50 years ago an ingenious engineer invented the duplex steam pump, standardized the type and in time built up an able and aggressive engineering, manufacturing and sales organization. Its success having been demonstrated, this type of pump was taken up by numerous competitors, each of whom developed a complete line, and a comparison of the bulky and closely printed catalogues with page after page of tabulations of sizes and models of duplex pumps issued by the dozen or so builders will indicate the immense amount of money invested in drawings, patterns and manufacturing equipment, not to mention catalogues and advertising. Partly because of pressure of competition, seven or eight of the largest of these concerns went into a merger and eventually into the hands of a receiver. All of their pumps, regarded as assets upon which to base a growing business, have now become practically obsolete, or at least greatly depreciated in value by the perfection of the more compact, simple, reliable and efficient steam-turbine-driven cntrifugal pump as used in all services from boiler feeding to city water works supply.

The Creation of Exclusive Markets.

The steam-turbine-driven centrifugal pump requires precise, scientific design, and accurate manufacturing methods, in order to secure both efficiency and reliability, but if some of the original pump builders had devoted a modest fraction of the time and money spent in copying other reciprocating pump builders to intelligently directed research and commercial development work he might, while continuing to supply the demand for reciprocating pumps then existing, have created a new and exclusive market for himself. It, however, remained for entire outsiders, steam turbine builders, to perfect and introduce the steam-turbine-driven centrifugal pump.

Second, we have, or should have, the inventor or research man. His endeavor specifically is to put the existing business out of business by bringing out something better. He must be an independent thinker, and his department is primarily a thinking and scientific intelligence department, largely free from dictation and direction by minds engaged in the routine of the business. The business man is generally about as good an inventor or research man as the inventor is a business man.'

Researcher-Inventor Must Have Broad Vision.

I have separated the research man from the designer, as it is not so necessary that the researcher-inventor should design as that he should be able to see things from both the maker's and the user's points of view, have a wide play of fancy and the power to co-relate facts. He reads everything. He may even at times take delight in considering the improbable or the unlikely from a spirit of mere novelty and adventure. The man who makes radical inventions is a man of vision, and perhaps of visions; he must penetrate the curtain of convention and habit. One thing is sure, he must not be overburdened with routine, must not travel in a rut and must never entertain the idea that anything has reached finality, or that he has done his utmost. He can quite properly be stimulated to venture freely in the quest for good ideas by some kind of contingent reward, something that will make the work interesting. He should not be discouraged by indefinite, intangible promises or by the offer of a mere fixed salary that may stop at any time.

A few concerns have grasped the value of always pushing forward; it is said, for example, that one automobile builder spends $500,000 per year in research and development. A great number, however, hardly do more than trust for their progress to the inconstant and flickering light of chance ideas.

Functions of the Designer.

The third member of our ideal technical business organization is the designer, the man who works ideas into shape for the shop and the user. While upon his sagacity and skill depend tremendous economies in manufacture, as well as satisfactory performance of the finished article, he is essentially conservative, a stand-patter, having a keen realization of the fact that every scratch of a draftsman's pencil costs money in the pattern shop, foundry and machine shop. The attempt to conduct research in the production department usually demoralizes the latter while rendering the research impotent. It is in this department that production branches from the line of our present discussion, and I shall therefore at once pass to the next member of the organization, the publicity or advertising man.

The advertising manager of a technical business should seek to grasp new ideas in their full import, and in all their implications, and endeavor to estimate and appreciate their possible and probable effects on existing practice and business. He works in close co-operation with the administrative, research and engineering departments, in order that he may understand what they have done and seek to do, and that he may formulate and popularize those ideas which will stimulate and guide customers' demands in conformity with their plans. It is his problem to tell the public how to use it, to make the product more thought of and better thought of, since the value which people will place upon the product naturally depends upon what they know and think about it. He endeavors to bring the user and producer closer together and seeks effective and economical ways for educating the user.

Clear, Forceful Presentation Essential.

His problem is a little different from that of the general advertiser. He must co-ordinate facts of physics, chemistry, engineering and commerce and infuse into them the spirit and purpose of a business. Exacting demands are made upon his breadth of view and industry, but at the same time, his work is facilitated because of the interest which naturally attaches to new things. There is nothing of human use to which interest does not attach, and anything that men have to do with can be made to interest them in some way. Engineers are naturally interested in new forms of construction, new theories and tests and descriptions of installations, and it is the advertising man's part to add pithy, succinct and forcible presentation.

In advertising to managers of enterprises, consulting engineers and others who purchase engineering appliances, he can to advantage appeal to their desire for further knowledge, and to the sentiments, beliefs and ideas of wideawake, self-reliant men, who probably have a large store of systematically organized knowledge which they will bring to bear upon the statements made to them. He must therefore argue logically and with a full command of the facts.

Utility of Products the Deciding Factor.

Engineering products are purchased almost solely for their utilitarian value. Their usefulness can be weighed, measured or computed in some way, they are usually purchased with much deliberation, for the reasoning faculties of the people who buy them have been emphasized by technical and business training.

The advertising should arise from and carry forward the general ideas and beliefs of the guiding mind of the business. It finds inspiration in new products and the exploitation of new fields. As compared with this broad purpose, the means and methods discussed in books on advertising, such as typography and display, color of ink, quality of paper, etc., are to a degree only incidental—all that is asked of them is that they should do their part in transferring ideas efficiently and not get in the way of the main motive, which is the making use of the spectacular qualities of advancement and improvement and the doing or saying of things interestingly.

The world is run largely on ideas and the dissemination of ideas is the business of the advertising engineer.

SOME TECHNOCHEMICAL PROBLEMS OF TODAY

By Dr. Raymond F. Bacon[*]

On May 14, 1915, Dr. Bacon Addressed the Chicago Section of the American Chemical Society on "Some Problems of Chemical Industry," Which Was Later Published, in Condensed Form, in The Journal of Industrial and Engineering Chemistry, Volume 7 (1915), 535. A number of Omissions Occurred in That Brief Report, and He Has Endeavored Herein to Supply, Principally for the Research Workers in Our Universities, the Additions Necessitated for the Completion of the Presentment. The Present Paper is Therefore Supplemental to the Paper Cited.

THEODORE N. VAIL, the distinguished organizer of the greatest telephone system in the world, has well expressed a recent industrial recognition:

> "Research, investigation, experiment, comprehensive and thorough, are now necessary to hold any position in any industrial or utility enterprise."

Mr. Vail attributes the success of his company—the nervous system of our economic and social structure—to the centralized, co-ordinated work of operation with research. Transportation, the circulatory system of the world, owes a similar debt to scientific investigation, for its development has resulted entirely from industrial growth, for which chemical inquiry is so largely responsible. It is now generally conceded that research and progress are synonymous as applied to manufacturing.[†]

The recent impetus imparted to the investigational activity in American chemical manufacturing has materially altered the traditional policy of industrial secrecy.[‡] This change in attitude, the direct product of the appreciation of urgent action in industrial research, has long been desired by our universities, and it will undoubtedly result in the extension of the practice of referring certain of the problems of industry to university laboratories for study. Many of the numerous problems of chemical manufacturing could be advantageously attacked outside of the plants; but some central organization, similar to the Committee on Research in Educational Institutions of the National Research Council, is needed for securing and properly distributing those problems which are pressing. It is clear, however, that stable relations between the universities and industrialists will be worth while only if some mutual benefits can accrue therefrom. This co-operation can therefore be most satisfactorily promoted by actively demonstrating the advantages of the exchange or interchange of subjects for research, which primarily presupposes a reasonable freedom from the concealment of knowledge which tenaciously adheres to all industrial research.

I shall now pass rapidly over a few of the many important problems of manufacture,[**] for the most part in the traditional industries—problems that a few years ago were either not given any consideration or were unknown, but which are now the subjects of considerable contemporary inquiry and even anxiety.

Some Present-day Metallurgical Problems.

A metallurgical problem which invites the investment of research with peculiar force is the concentration of the so-called brown-ore of Virginia, Tennessee, Kentucky, Georgia, Alabama, and Texas. Calcined brown-ore carrying more than 50% of iron is readily marketable and it is said that processes of the type of the Goltra method may be profitably applied not only to these deposits but also to brown-ore "banks" which cannot be worked by old methods of preparation. Other iron-ore problems are the economic utilization of the aluminous ores of Tennessee and of the siliceous potash-bearing ores (gray iron ores) which occur in other southern States.

In blast-furnace practice, there is needed some method of increasing the basicity of the slag without increasing its temperature; very little information is available regarding the amount of sulphur which can be expelled with the top gases; the control of manganese is comparatively incomplete; little is known of the general subject of the effects of variations in the carbon contents of the different kinds of iron, and consequently we are unacquainted in detail with methods for the systematic control of carbon; and there is a lack of exeprimental knowledge relating to the action of a considerable percentage of vanadium in the blast-furnace charge. Reference may also be made here to the problem presented in the production of ferro-vanadium alloys directly from iron ores containing vanadium; this is difficult because vanadium goes into slag very readily.

Other Problems in Siderurgy.

The following are some of the many other problems in siderurgy: the recovery of manganese as an alloy from slags high in manganese; the extension of the commercial uses of open-hearth and converter slags, particulaly a broad study of their use in ceramics; the improvement of the quality of cast-iron or pig iron of ordinary coke grade, to make it the equal of higher-priced charcoal iron; the influence of B-iron on the hardening of steel; the relative merits, as regards corrosion, of various iron products, and especially pure iron as compared with ordinary open-hearth and copper-bearing steels;[*] the cause of internal transverse defects in rails; satisfactory substitutes for imported magnesite as an iron and steel refractory (zirconia is too costly)—this problem actually resolves itself into how to use domestic magnesite—and for graphite as a foundry facing; the cause of the lack of success in the use of ferro-silicon to replace entirely the ferro-manganese in the deoxidation of steel; and the possibility of recovering by-products from blast-furnace gases, such as compounds from which cyanides might be made.

[**] In collating these I have drawn from all available sources of information and especially from my experience at the Mellon Institute.

Mention has been made in several other communications[†] of certain of the problems encountered in the metallurgy of zinc. The treatment of flotation concentrate is one of the present troubles of the zinc smelter, owing to its great fineness. While the proportion of this grade of ore which the smelter is obtaining is still small, the supply of it is, however, certain to increase. The roasting of ferruginous blende in such a manner as to convert all of the zinc into sulphate and oxide, avoiding the formation of sulphite and ferrite, is another interesting subject for research. Two other problems in this field are the manufacture of retorts of higher tensile strength and greater durability, and the relation of the elements of the ash ingredients of the reduction fuel to the same elements in the ore, having in mind a more satisfactory blending of the ore and the reduction material.

Leaching and Flotation.

The increasing adaptation of flotation to the treatment of low-grade copper ores has somewhat discouraged the use of leaching methods and accordingly these processes have not made the progress expected; but the field is still open for oxidized ore where flotation has not thus far been successfully applicable. Successful flotation assumes that the copper content of the ore is in the form of disseminated mineral. In the case of ores in which the copper compound is diffused throughout a mass of gangue, such as is undoubtedly true of the copper silicate ores found at Inspiration, it is certain that flotation is out of the question and that some leaching process must be used.

The acidity of the gases from copper and lead smelting works presents a problem which still awaits solution. In electrical precipitation, the treatment of enormous volumes of gases in the smelter flues introduces several problems: in addition to the magnitude thereof, there are the problems connected with the handling of the fumes and dust and their metallurgical treatment. It is, of course, possible at present to separate from certain fumes thousands of tons of arsenic annually and it would probably be feasible to separate an amount of sulphur which would run into hundreds of thousands of tons annually, were there markets for such quantities of these by-products. The problem therefore resolves itself into the establishment of new tonnage uses for arsenic and sulphur.

Metallurgy of Precious Metals.

In the metallurgy of the precious metals, the high price of zinc has stimulated renewed study of electrolytic methods of precipitation (the new plant at Great Falls, Montana, is illustrative of the trend in this direction) and a large amount of experimental work is in progress on the application of the flotation process. In the case of concentrate produced by flotation, the minerals composing the product are substantially the same as those obtained by gravity concentration, consisting of the sulphides and the double sulphide of the heavy metals, and therefore similar difficulties are encountered in their treatment.

Other more familiar metallurgical problems are the prevention of zinc loss in the brass industry, the elimination of arsenic from antimony, and the cheap deoxidation (retrieving) of aluminium remelted from scrap; but after all the conservation of our metals and their protection after they have been manufactured and put into service holds out most interest.

Utilization of Alkaline-Earth Elements.

Among the less used metals, the alkaline-earth elements are begging utility. There is no doubt that calcium could be produced economically even by methods now known if it were manufactured on a large scale to fill an extensive demand, but markets therefor must first be established by the discovery of important new uses. Results of commercial significance might be obtained by the investigation of the alloys of calcium and of its application as a chemical purifying agent in melting and casting metals. Calcium has been used in Germany as a substitute for ferro-manganese in the deoxidation of steel. In the cases of barium and strontium, uses could be developed if methods were known by which these metals could be isolated cheaply; while with magnesium an electrolytic method is required which will enable its producton for about 25 cents per pound (direct reduction of the oxide, as in the case of alumina, is suggestive). Beryllium is another metal whose properties should receive broad investigation, for at present its known uses do not justify its cost.

---

[*] Because of the immense amount of research which has been carried out on this subject, I have hesitated in citing the above-mentioned problem as unsolved. However, the fact that controversy still prevails places it in that class. Personally, I believe that the use of copper-bearing steels have much the best of the argument.

[†] See Bacon, Science, N. S., 40 (1914), 877; and I. Ind. Eng. Chem., 7 (1915), 535.

Production of Chromium.

The production of boron and ferro-boron of uniform quality requires expert study. Cheap and pure chromium is now unobtainable; the electrolysis of its fused salts is difficult on account of their high melting-points, but perhaps the electrolysis of aqueous solutions of chromium salts could be so controlled that heavy deposits would be produced. Then, too, chromium electro-plating is for many purposes superior to nickel, but the technique of constantly producing perfect plating has not been accomplished.

Since there is no lack of raw materials, broad study should be made of the methods of producing pure titanium and zirconium and of their prospective uses. The same statement also applies to molybdenum, although the greatest need of the molybdenum industry at the present time is a more economic utilization of its sources of raw material: in general, the deposits have been neither properly prospected nor opened up, and then not wisely worked; and loss and waste should be minimized as the result of a careful investigation of crushing and concentrating methods. However, the relatively small tonnage of molybdenum needed at present is a handicap in the exploitation of its ore deposits.

Other Problems of Industrial Inorganic Chemistry.

There is real need of extensive experimental research on the chemical character of coal. The knowledge regarding the combustion and distillation of coal is principally empirical, and will of course remain so until a clearer insight is had of the actual nature of the complex compounds contained in the coal substance and of the mechanism of their decomposition by heat. Two very important problems in the preparation of coal for the market have to do with "wastes": the production of an absolutely smokeless fuel in the manufacture of briquettes from anthracite culm; and the utilization of the high-ash (60—75%), high-sulphur (5—10%) waste from bituminous coal washers.

Many other problems exist in the domain of mineral technology. New uses are desired for tripoli; the Gypsum Industries Association is engaged in furthering the development and advancement of the uses of gypsum; and the employment of slate in the manufacture of blackboards and school "slates" has so decreased that new applications are wanted to replace this loss of market. Then there are the problems in connection with the use of the natural abrasives, emery and corundum; one still hears of the sudden and wide variation in the composition of different shipments; but since the development of high-grade artificial abrasives and the exploitation of larger corundum deposits in Ontario, no corundum has been produced and only a small quantity of emery has been mined in the United States, and accordingly new uses are being sought for these minerals. The abrasive garnet market is also strictly limited and shows little tendency to extension at present. Reference may be made here to several problems in the technology of fuller's earth, the literature of which is meagre and unsatisfactory. Little is known regarding the qualities of fullers' earth which adapt it to its applications; there is a needless obscurity concerning the changes which it occasions in oils and to which it is itself liable; it is not clear why certain earths possess a tendency to cause spontaneous combustion in the material from the filter presses; and, finally, what is the cause of the malodour which sometimes accompanies the use of a particular earth?

The problem of commercially separating a soluble potassium salt from brine containing sodium chloride, carbonate and sulphate and other salines remains unsolved; the cleaning and drying of phosphate rock should be done more economically; and the regenerative system of heating has not been profitably applied to the pottery industry. In fact, an attractive variety of problems is found in all sections of the inorganic field, and many—particularly a compact apparatus for generating hydrogen which could be erected on a freight car and easily conveyed about for Governmental purposes; the economic production of nitric acid from ammonia by the catalytic process; the development of a commercial process for manufacturing aluminium nitride; and the direct preparation of hydrated solium carbonate in a stable, powdered form, and of sodium silicate in a readily powdered, solid, soluble form—might be attacked to advantage outside the purlieus of industry.

Refractories.

However, of all the anxious inquiries coming in from our manufacturers, those pertaining to refractories possibly possess the most notable academic interest. What is the exact inversion point of the crystalline form of calcium oxide? Why is the porous form of calcium oxide so much more reactive than the crystalline? What are the physico-chemical properties of ferrous oxide at high temperatures? What are the relations of the inversion points of the iron oxides to one another? Can alumina be satisfactorily made (sintered) into a dense, hard refractory without the aid of a bond, thus obviating the troublesome shrinkage which occurs at temperatures far below the melting point of alumina? And finally there are the troubles in the case of refractories for open-hearth furnaces. The principal source of difficulty is the slagging tendency of the dust, which is derived partly from the producers and partly from the charges. Perhaps a satisfactory means of suppressing the dust might be devised, but another possible way out of the trouble might consist in replacing the acid bricks of the checkerwork by basic ones. Magnesia and bauxite bricks have been tried, but are liable to shrink; this weakness might be overcome in the case of bauxite bricks by burning at a sufficiently high temperature and by suitably modifying the texture and composition. Dolomite bricks have not been experimented with.

In fact, it sometimes seems to me that the greatest single problem in chemical technology is the one of refractories. There are many industrial problems that now appear to be impossible of commercial solution, which could be immediately solved, provided we had some ideal refractory substance which would retain its shape and strength at high temperatures and would not be acted upon by the acid or alkaline constituents of a charge or by the gases evolved during the reaction.

Problems of Industrial Organic Chemistry.

The inquiries which come from the domain of organic technology are well illustrative of the opportunities which exist for co-operative research, as well as explanatory of the existing anxiety for new ideas in manufacture. More numerous, perhaps, than any others, are queries regarding coal products and their manufacture.

In particular, the problems in connection with the by-product coking of coal are of especial importance at the present time. It is generally conceded that "coke breeze" is not being utilized in the most economical manner; new uses should be found for pitch and coumarone resin; the acid tar from the chemical treatment of light oil should be recovered and worked up; and, for availability in times of peace, there should be accumulated a reserve of knowledge on new uses for benzene and toluene.

The related tar distillation industry represents the following problems:* What is the cause of corrosion in tar stills? Is the present method of separating fractions the best, in view of the products required? Uses are also wanted for creosote oil and for lesser known bodies in the distillates; there is required a broad investigation of coal tar pitch to discover ways of rendering it more suitable for replacing natural asphalts; and the methods for testing coal tar products should be standardized. Two questions which have arisen in the manufacture of coal gas are worthy of mention in this place; these are: Have we exhausted the chemical possibilities of by-product or retort coal gas when we have recovered from it the ammonia it contains; and is it feasible to make gasoline from coal gas? This last problem does not appear to me to be commercially practicable in America, but it is under consideration in England and other countries which produce no petroleum.

The Petroleum Industry.

The numerous problems of the petroleum industry have been considered at length elsewhere,† but references may be made here to several problems of the Scottish shale oil industry. Much remains to be learned regarding the best conditions for the production of crude shale oil, in particular the form of retort and the temperature of working; 80 to 85% of the raw shale put into the retorts is sent to the waste heaps as spent shale, the utilization of which has not been the subject of sufficiently extensive research; and the refinery tars, now used as fuel, could be investigated with the object of separating commercially valuable substances. These problems are of more than mere passing interest to American chemists on account of the probable early development of certain of our oil-shale deposits.

The problems of technical photochemistry are of considerable economic importance. Many of our plants are wasted either because of a lack of knowledge regarding their possibilities or because of a deficiency of interest in their industrial development. The processes for obtaining rubber from guayule sap are unperfected; the method employed for extracting wax from candelilla is crude; algerita and osage orange contain dyestuffs, but have received practically no attention; the commercial possibilties of mesquite seed and wax are unknown, and the same statement applies to the wax or gum from prickly pear cactus; no suitable process is known for degumming ramie fibre and making it suitable for spinning; there is no knowledge of the industrial possibilities of bear grass; the use of rice straw and cotton stalks as paper-making materials requires more study; and the castor bean, sunflower, and camphor tree are well adapted to the coastal plain of Texas and should constitute the bases of well-established industries.

Problems of the Cotton Industry.

The cotton industry holds out engaging opportunities for chemical research. The following are some of the problems which confront the planter of cotton: What is the action of various fertilizers on the yield of cotton and on the quality of the fibre produced? Are there available any fertilizers which can be substituted for potash, and, if so, what conditions must be observed in their application to the soil. Can a chemical treatment be devised for destroying the Mexican boll weevil, or at least rendering it more harmless? And then there are some problems in preventing the production of stained cotton during seasons of excessive rain, and in bleaching a stained cotton a pure white.

The chemist has been of inestimable value to the wood turpentine industry. In addition to developing processes and designing suitable plants, he has standardized the products, created markets therefor, and found uses for the important by-product, pine oil. However, there are still opportunities for other chemical contributions. Fresh crude turpentine contains normally about 30% of spirits of turpentine, but under the most improved methods of collection and distillation in use at present, yields of only 18 to 20% are obtained; this loss of at least one-third of the volatile oils remains to be overcome. The French method of bleaching rosin is slow and otherwise uneconomic, but the chemical methods which have been proposed are unsatisfactory; methods of distillation by the use of superheated steam or vacuum, although apparently desirable, have so far had no altering influence on methods of manufacture; and the disadvantages of wood fibre from turpentine production as a source of pulp remain to be overcome. Notwithstanding its charcoal and bark contents, this fibre is said to produce a satisfactory grade of brown wrapping paper, and there is now some activity in this utilization. The question of substitutes for wood in the manufacture of paper pulp is a pressing one, and any source of relief is gratifying. Perhaps the manufacture of tannic acid extract from palmetto roots and other sources might be made profitable by the production of paper pulp from the fibre residue.

---

*On other problems of the coal-tar industry, see Bacon, J. Ind. Eng. Chem. 7 (1915), 535.

†Bacon and Hamor's "American Petroleum Industry," 1916, 2, 798-807.

Other problems in the organic branch of chemical industry are the production of a satisfactory butter-substitute from soya-bean oil, the cheap extraction of vitamines from rice hulls and from yeast, the recovery of the wax occurring on the outer surface of the sugar cane, and the economic production of ammonia from sources in the various stages of beet sugar manufacture.

Some Needed Commercial Syntheses.

The many opportunities that lie everywhere at hand in this entire field, and particularly in pharmaceutical chemistry, make one frankly consider why expert organic chemists should devote laborious days to preparing some substance of purely academic interest, while there is urgent need for practical working processes for the synthesis of atropine, cocaine, morphine and quinine. One is reminded of Chesterfield's remark that:—

> "Very few people are good economists of their fortune, and still fewer of their time."

when this mismanagement of laboratory resources is further evidenced by citation of the following instances of desired commercial syntheses: formaldehyde, acetic acid, amyl alcohol, tartaric and citric acids, sanguinarine, hydrastine, caffeine, and nicotine.

A favorable occasion for industrial service also exists for the physical chemists of our universities. To mention one illustration from the field of organic chemistry, but little progress has been made in the employment of light in the manufacture of such chemicals as the chlorides of carbon, although photochemistry has developed into an important theoretical branch. Light is a powerful, uncontaminating catalyst for effecting certain chemical reactions, and the white flame arc has opened up many possibilties for controlling and altering oxidation and halogenation processes.

The problems listed above represent only a fraction of those which might be disclosed, but they are illustrative of the opportunities for applying scientific knowledge and investigational methods to the domain of industry. On every side, the research men of our universities are needed for the execution of real attainments in the technical world, with its difficulties, and unexplored lines of manufacturing.

CONVERSION OF BARIUM AND RADIUM TO CARBONATES

Methods for Carrying on This Reaction at Low Temperature Reported by U. S. Bureau of Mines Experiment Station.

The Golden, Colorado, Experiment Station of the Bureau of Mines, Department of the Interior, reports that it has been found that, by fusing radium barium sulphates carrying a considerable proportion of silica with a mixture of caustic soda and sodium carbonate, the whole of the barium and radium are converted into carbonates. The amount of sodium carbonate required is comparatively small, 10% to 15% only being required. The reaction goes at a low temperature, and the difficulties of fusing with carbonate alone are entirely eliminated. The product is also much more easily washed free from sodium silicate.

The equipment and installation of the technologic laboratory at Golden have been almost completed. The laboratory is designed to handle rare metal ores in quantities from 10 lbs. to 500 lbs. It is designed to make any kind of an acid leach; any kind of an alkaline or salt leach; and any kind of a fusion. In addition a small Wedge type roasting furnace has been installed as well as a tube furnace which can be used either for oxidation purposes or for reduction.

SHORTAGE OF AMMONIUM SULPHATE FOR JAPANESE

From Consul-General George H. Scidmore, Yokohama, Japan, comes a report to the U. S. Bureau of Foreign and Domestic Commerce regarding the shortage of ammonium sulphate in that country owing to the cessation of imports from England. A portion of his letter is printed in the daily report of the bureau, as follows:

"Supplies of sulphate of ammonia in this country states the Japan Chronicle, are becoming increasingly short. Japan gets its imports principally from Great Britain, but shipments thence have greatly decreased. During December, 1916, Great Britain exported 23,029 tons, bringing the total exports for last year to 259,300 tons, a decrease of 35,000 tons from the quantity for the preceding year. Of last year's total exports from Great Britain, shipments to Japan amounted to 9,155 tons, a decrease of 1,382 tons compared with the preceding year. Lately shipments to this country have practically stopped, and a cablegram received in Osaka says that no shipments will be possible for the present.

"Sulphate of ammonia is produced in this country but the output is insignificant—not more than 3,000 tons a year—while last year's consumption in the Kobé and Osaka districts alone amounted to about 7,000 tons."

A NEW FLOTATION OIL

And a New Source of Flotative Agents.

By Oliver C. Ralston.*

In His Discussion of the Papers of Maxwell Adams and G. H. Clevenger, presented at the Arizona Meeting, American Institute of Mining Engineers, the Writer Gives Numerous Interesting Cost Data in the Hope That Further Experiments May Be Undertaken to Determine the Economic Merits of Sagebrush Oil as a Flotative Agent.

WE are indebted to these two gentlemen for the work which they have done with the oils derived from sage brush. Their work should not be confused, however, as the work of Mr. Adams deals with steam-distilled oils and that of Mr. Clevenger with destructively distilled oil, largely. In other words, Mr. Adams' oil is probably the original essential oil that existed in the brush before distillation while Mr. Clevenger's oil not only contained this essential oil but also some products of destructive distillation of the wood constituents.

I had noticed the work of Mr. Adams on attempting to separate the various constituents in the oils of some of the Western conifers and had sent to him to ask if he could send me small samples of some of these pure products. This he very kindly did, and with them included some samples of oil from the common sage brush, whose characteristics he has here described, as well as a sample of oil from the common "rabbit brush." Only the sage brush oil proved of much value for flotation, but it was very powerful, and I so informed Mr. Adams. Even in amounts as small or smaller than one-tenth pound per ton of ore, it gave very quick and positive flotation of many ores, with high-grade concentrates and good extractions. It proved to be especially desirable for the flotation of carbonates of lead and of copper which had received an artificial coating of sulphide by treatment with a solution of a soluble sulphide.

I also received a sample of crude pyroligneous acid from sage brush prepared by Dr. W. C. Ebaugh, of Salt Lake City. It did not do very good work in flotation, but it is possible that by concentration of this product to obtain the residual tar a good flotation oil might result. This has not been done as yet and I am sorry to see that Mr. Clevenger has not done this. It might be that the dissolved tar, added to the settled tar, would make a total yield of flotation oil higher than the 4 per cent. which Mr. Clevenger feels is a safe estimate. The importance of this point will be seen in the following discussion of the possible costs of sage brush oils for flotation.

I have been fortunate in obtaining the approximate costs of collecting sage brush, as well as the costs of operation in the ordinary wood-distillation plants. I was given the former by E. H. Snyder, who with a number of associates cleared some land of sage brush and made potash from the ashes of the burned brush. The latter were given me by R. C. Palmer, formerly of the Forest Products Laboratory of the Department of Agriculture.

The clearing of land of its sage brush is ordinarily accomplished by means of a tractor pulling a special frame made up of railroad rails. This breaks off the brushes so that they can be collected in hay ricks and hauled to a central point. For merely uprooting the plants and burning them on the spot the cost is about $4 per acre, but to recover them and take them to a central point ready for burning or distillation, costs about $6 per acre.

Mr. Snyder further informs me that with the average 4-ft. stand of brush in southeastern Nevada the yield per acre is about 7 tons of brush. I am informed that there are considerable stretches of country around Bear Lake in Idaho and Utah where the brush is nearly 10 ft. high. Hence considerably higher yields might be possible. However, we can take as a safe figure $1 per ton for cutting and collecting the brush to a central point.

The cost of destructive distillation of hard wood is in the neighborhood of $8 per cord (4,000 lb.) of wood, or about $4 per ton—possibly $5 per ton of wood. While the sage brush might be more bulky than the wood, and hence cause higher costs, this factor can not be estimated at the present time and it is probably best to count on a distillation cost of $5 per ton.

That would make the total cost of treatment of each ton of sage brush about $6, and the yield, according to Clevenger, is 4 per cent. or 80 lb. of tar. This would mean about 10 gal. produced at a cost of $6, or $0.60 per gallon, or 7.5 c. per pound. This is rather high but is comparable with the present price of pine oil, of which sage brush oil seems to be the full equivalent, if not the superior. With most ores, less than 0.5 lb. of sage brush oil should be needed per ton of ore.

If Clevenger's figure of 4 per cent. yield of oil could be raised to 6 per cent. by addition of the dissolved tar from the pyroligneous acid, the cost of the oil would be about 43 c. per gallon. Further, if greater yields of brush from each acre were obtainable, the costs would be cut slightly, although this point is not of so much importance, as the principal costs are due to the distillation. It is also possible that in some cases owners of the land would be glad to pay $1 to $2 to have their land cleared of brush, where it would usually cost them about $4. Only skilful management and the choice of the proper regions for operations would probably bring in this latter source of income.

---

*From the November Bulletin of the American Institute of Mining Engineers. Discussion of papers of Maxwell Adams and G. H. Clevenger presented at the Arizona Meeting, September, 1916, and printed in Bulletin No. 117, September, 1916, pp. 1683 to 1684 and 1685 to 1692.

There is one other source of income from the products of the sage plants, namely, the potash. Mr. Snyder informs me that he found the potash in carefully burned brush ashes to amount to 15 to 20 per cent. of the total weight. Most of this was soluble in water but the remainder was "acid soluble K_2O." The ash amounts to 7 to 10 per cent. of the weight of the plants. Hence the K_2O content of the brush can be estimated as from 1 to 2 per cent., or 20 to 40 lb. per ton of brush. In normal times potash is worth about 3 c. per pound. This would make the value of the potash in the brush about $0.60 to $1.20 for every ton. The cost of leaching and crystallizing the potash from the aches is unknown, but might possibly be $3 on every ton of ash or 20 to 30 c. referred to every ton of brush. It is not impossible that the burning of the sage brush charcoal under the boilers of the distillation plant, followed by leaching of the ashes would yield potash of sufficient value to allow a profit, and hence allow of production of sage brush oils for flotation at a lower net cost than the above rather pessimistic figure. One difficulty at the potash end of the work is that it tends to be carried away in the combustion gases and a Cottrell precipitator might have to be used in order to insure recovery of all the potash.

The above is merely a suggestion to show what might be expected if one were to attempt the commercial production of sage brush oil. Rather high costs were assumed, but it is certain that other sources of expense than those enumerated will make such a pessimistic figure desirable, for the sake of safety.

About 10,000 gal. of steam-distilled pine oil are being used every month in the United States for flotation purposes and more would be used if the price were lower. The last quotation that I heard for pine oil was 67 c. per gallon, f.o.b. New York. If sage brush oil could be produced for 40 c. per gallon it is probable that the market would jump to at least 25,000 gal., or roughly 1,000 gal. per day. With this would be produced 3,000 to 4,000 lb. of potash, an amount which is much less than 1 per cent. of the total consumption in the United States. Hence the sale of potash from such a source should have no bad effect on the market. On the other hand, if the oil could be produced for 25 c. per gallon, there is no reason why its use should not amount to 10 times the consumption of the oil at a 40-c. rate.

It is to be hoped that these figures are attractive enough to cause experimentation on a reasonably large scale, to determine whether operations can be profitable. Only by such a method can it be estimated whether we have a new source of flotative agents and a new source of potash.

BARRETT COMPANY INCREASES CAPITAL.

Announcement has been made by the Barrett Company of an increase in its capital stock from $20,000,000 to $37,500,000.

JAPANESE AND AMERICAN OILS IN SOUTHERN CHINA

Aided by High Freight Rates, Japanese Producers Enter Hongkong Trade Field In Competition With Americans.

Under date of February 9, Consul General George E. Anderson writes from Hongkong to the United States Bureau of Foreign and Domestic Commerce as follows:

"The high freight rates which have obtained during the past two years on all cargo from the United States to the Far East have caused a big boom in the production of petroleum in Japanese territory and a great increase in the sale of Japanese oil in the Hongkong trade field in competition with American and East Indian oil. Immediately previous to the war Japanese oil had secured a foothold in this field, particularly in the Foochow, Swatow, and Amoy districts. Imports of Japanese oil into all China increased from a value of $108,550 in 1913 to $161,615 in 1914 and $945,855 in 1915. Much of this increase was in the districts mentioned, and it was largely at the expense of American oil trade, the Japanese product representing about a quarter of the whole in those districts in 1915.

"During the past year there has been a great development of the trade because of the constant rise in freights from the United States. Previous to the war, oil enjoyed exceptional treatment. It was used largely as reserve cargo, and was carried at the lowest freight rates, usually rates much below the market. Since the contraction in tonnage due to the war, however, kerosene has paid rates in proportion to other cargo, rates on oil during 1916 from the United States, in fact, being substantially five times what they were previous to the war. Naturally Japanese oil, with the short haul from Japan in subsidized vessels carrying the oil at rates fixed by the Japanese Government, has had an immense advantage. The price of oil in Japan has increased immensely during the past year, but most of the time the price of such oil for export has not increased in proportion. The home market in Japan is reported as booming as a result of the decreased import of foreign oil due to increased prices and higher freights. All these conditions are resulting in the development of strong oil interest in Japan and Formosa which promise serious competition for American oil in the future.

"Because of the scarcity of tonnage and high freight rates, also because of disturbed conditions in South China, the consumption of petroleum and its products decreased about 40 per cent during the year. Nevertheless prices remained about the same as they were at the beginning of the year. Stocks have been greatly reduced and will remain low until freight rates are reduced."

COMPARATIVE TESTS WITH MANGROVE AND WATTLE BARKS

By

F. A. Coombs, F. Alcock and A. Stelling*

In Making the Tests Herein Recorded, the Writers Used Principally the Rhizophora Mangrove. It Was, However, Impracticable to Keep the Different Kinds Separate, and Experiments Were Made with the Ordinary Commercial Mixed Bark. Tests Were Made Alternately to Guard Against Any Possible Variation in the Right and Left Halves of the Hide. No Experiments Were Made on Soaking at 45° C.

THE mangrove barks are now being used in large quantities by tanners who are producing sole-leather. These barks have a very high tannin value and very large supplies are available for the production of leather.

In a previous paper** we gave the tannin values of some Australian mangrove barks. After examining the mangrove trees in Cairns and Cooktown districts, North Queensland, we found that *Rhizophora mucronata* represents fully 75% of the trees suitable for stripping, the remainder consisting largely of *Brugiera gymnorrhiza* and *Ceriops condolleana.* For commercial reasons strippers are not likely to take the bark from the different species and keep each one in a special grade. The above three species† grow in a very mixed state and buyers can assume that bark from these districts consists of an excess of *R. mucronata* and small varying proportions *B. gymnorrhiza* and *C. condolleana.* The majority of the mangrove bark from German East Africa‡ is also taken from the above three species.

We have used the commercial mangrove bark for our tanning experiments, and *B. gymnorrhiza, R. mucronata*, and *C. condolleana* were examined by the aid of the usual qualitative tests.

Values for Mangrove.

The color and precipitation tests gave results which did not differ from those described by other workers for the mangrove bark. The solubility tests for mangrove tannins have not received a great deal of attention from leather chemists, and the results given for these tannings may have been obtained from one or a mixture of the genera which are described as mangroves.

The following values have been given§ for mangrove: Ethyl acetate figure, 0 to 5; alcohol figure, 0 to 5, and gallic acid value, 0.68.

These differ to a certain extent when compared with our results shown below.

TABLE I.

	C. condolleana.	*R. mucronata.*	*B. gymnorrhiza.*
Ethyl acetate figure	20 to 25	7	4
Alcohol figure	0	0	11, 12, 24
Gallic acid value	0·785, 0·738, 0·692, 0·657	0·600, 0·595, 0·501, 0·479	0·450, 0·385, 0·381, 0·359

Proctor and his students have carried out a considerable amount of work in connection with the oxidation of tannins with permanganate and the results obtained are useful as qualitative tests for the recognition of various tannins. He gives the gallic acid value of one grm. of chestnut tannin as varying between 0.56 and 0.66 and of valonia tannin as varying between 0.55 and 0.63.

Variations Common to Mangrove.

These variations are common to mangrove and apparently no constant figure can be given which represents the gallic acid value of these tannins. The gallic acid value of mangrove tannins apparently reaches the maximum with *C. condolleana* and the minimum with *B. gymnorrhiza.* Proctor states that the phlobaphenes or reds are probably anhydrides of their respective tannic acids, and it is a well-known fact that the catechol tannins change on exposure to heat or light from a medium to a dark red color. This change brings about a more complicated and larger molecular aggregate; and as this aggregate increases its solubility in water decreases, until it finally reaches the state known as insoluble reds of phlobaphenes. The tannins in wattle and mangrove barks appear to exist as variable molecular aggregates ranging from the parent body, or unit molecule, to the insoluble red; and it is probable that the oxidation values would differ for the unit molecule and the difficultly soluble reds. The tannin from *B. gymnorrhiza* has a low oxidation figure and probably a high molecular aggregate. Mallet bark tannins also have a low oxidation value (gallic acid value, 0.288) and the rate of penetration is slow.

Recently Bennett (J. Soc. Ind. Chem., 1914, 1182) suggested certain changes in the I. A. L. T. C. official method for estimating tannins. He believes that the present method returns a high percentage of non-tans, and we are confronted with the problem that certain substances exist which are tannins or non-tannins according to the ratio, within certain limits, between hide-power and tannin.

Oxidation Figures Wanted.

The non-tannins have a low oxidation figure and it would probably throw some light on the subject if oxidation figures were obtained for tannins and non-tannins from one sample of bark, using both the official and Bennett's revised methods for estimating the tannin. Such results would show if the substances under dispute were akin to tannin or non-tannin, and we might get a better view of the value of the gallic acid figure.

The leather-forming properties of mangrove barks were tested by an experimental process described in *Collegium.**

Two duplicate tests were carried out for comparative purposes, and wattle bark was used for the standard tannage. The mangrove bark has already been described and the wattle bark was the same as the tanners use under the name of Adelaide bark (*Acacia pycnantha*).

Division of the Hide.

The hide is cut into sections of equal area and numbered as shown in the diagram. The sections are approximately 1 ft. 9 in. square and they are soaked, limed, and tanned in upright vats measuring 2 ft. x 2 ft. x 4 in. Two sections are suspended in each vat and about 32 litres of liquor is required to cover them.

The sections 1 and 5, 2 and 6, 3 and 7, and 4 and 8 are approximately constant in area, thickness (substance) from grain to flesh, and in general structure.

The first two sections, Nos. 1 and 5, are both soaked, limed, and delimed in the same vat at the same time; therefore temperature, time, and constituents of all liquors are constant for these two pieces until they reach the tan liquors. Then they are separated and No. 1 goes into wattle-bark liquors and No. 5 in mangrove liquors. Under skilled control these two sections are approximately constant until they reach the tan liquors, and then if any variation occurs it will be due to a difference either in the process of tanning or in the tanning materials. In this experimental work the tanning process has been kept approximately constant for both duplicate tests, so that if the hide sections be constant the variations can be traced to difference in the tan liquors (acidity, non-tans, etc.) or in the structure of the tannin molecule. What has been said of Nos. 1 and 5 applies also to the groups Nos. 2 and 6, 3 and 7, and 4 and 8, but it is hardly necessary to point out to practical men that No. 1 will differ from all others with the single exception of No. 5 section, and likewise No. 4 will differ from all except No. 8 section.

Results of Two Tests.

Sections 1 and 5 and 2 and 6 were used for the first test and the other two pairs were used for the second. For both the soaking occupied two days with two changes of water; liming seven days in one fresh lime liquor; wash pits (after dehairing, etc.) two days, with two changes of water; and deliming one hour in lactic acid solution (2 grms. per litre).

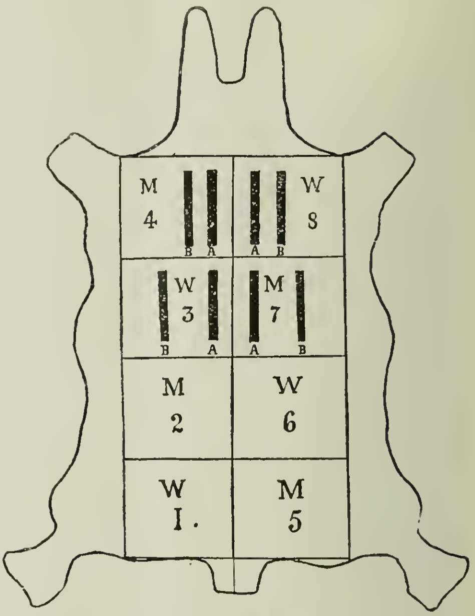

Diagram of Ox-Hide.

The tanning process was continued at a constant tannin strength for both tests.

Acidity of the mangrove liquors for both tests is higher than the wattle liquors, and one might therefore expect the mangrove leather to fix more tannin. However, we are now carrying out comparative tests for the value of acid in tan liquors and hope to discuss this point at a future date. The variable ratio between tannin and specific gravity is fully demonstrated in both tannages. The wattle tannins penetrated the hide quicker than the mangrove tannins.

Figures Show a Small Irregularity.

The figures for the tanning process show a small irregularity due to the process of extracting the tannin from the bark. We are extracting tannin from the bark at irregular intervals and some liquors had a short time for exposure to fermentation. The amount of difficultly soluble tannins was low for these tan liquors, and these conditions might adversely affect the percentage of combined tannins.

The following are results obtained by weighing each section after it was taken out of the various tan liquors. The pelt weight is taken at 100 and the percentage in-

28	117·06	60·0°	15·3	62·1°	9·6

crease is added to that figure. It will be noted that the increase is higher with the mangrove tannage, but the increase for both tannages is lower than the amount representing combined tannins, and therefore we can assume that as the hide takes up tannin water is expelled.

Sections 1, 2, 5 and 6 were taken from the tan liquors and suspended in water for two hours, drained overnight, scoured on the grain, oiled, and then finished as sole-leather. Sections 3, 4, 7, and 8 were washed in water and allowed to dry. These sections did not receive any oil. The dry rolled sections were what tanners call "firm" but not hard. The mangrove leather was a bright, clean red color. The dry unrolled mangrove-tanned sections were not inclined to a brittle grain, so that scouring is not a necessary factor in the finishing process.

Analytical Results.

The analytical results are worked out on a leather free from fat. The sum of water, total solubles, combined tannin, and hide-substance is 100%. The nontannins are very low, suggesting that the total solubles include free tannin, which was originally combined tannin. Total solubles were extracted from the leather shavings at a temperature of 45° C. The time for extraction was three hours. Previous experiments with pine and wattle barks show that the degree of tannage is low for these mangrove and wattle tests. This difference is partially explained by the fact that we used a thicker hide for this experiment. Another matter would be the age of the leather. For the pine bark experiment the leather was not analyzed until ten months after it was removed from the tan liquors, but for this experiment the same work was all completed within one month. It has been proved* that the catechol tannins, both free and combined, are gradually changing in the air-dried leather. Probably this change adversely affects the solubility of these substances and the natural result would be a lower figure for total solubles. When leather is placed in water at 45° C. it apparently releases a certain amount of combined tannin, so that, omitting bloom and reds, a final and approximately constant figure might be obtained for mangrove tannins. We carried out a second extraction for Sections 4 and 8, and the usual standard process was repeated daily for four days. The results obtained brought the degree of tannage down to 32.7 for mangrove and 31.8 for wattle; after several days the mangrove (in water 18° C.) was still giving up a little coloring matter, and it seems probable that under these conditions we could have reached 30 as a final figure for both tannages.

Further Experimental Work Necessary.

The stability of the combination of hide-substance and tannin, as shown by the degree of tannage, varies to a considerable extent according to the process of extraction, etc. We took four pieces out of each section, when sampling for analysis, and the samples from the two sections in each group were in the same water bath during the process of extraction; so that the results show differences between the two sections of any one group under approximately constant condition. We have to compare results from leather shavings with results from leather ground in a mill,† and if

higher total solubles were obtained from the latter then it would appear as if these tannins produce a very unstable leather. However, we recognize that we must carry out more experiments in connection with this problem of extraction.

From a commercial standpoint the leather weight returns, calculated on the pelt and green-salted weights, are all in favor of mangrove.

The water absorption test was carried out by placing the unrolled sections in water for various periods as shown below. The leather weight, calculated free from water, is taken at 100, and the water absorbed is shown as a percentage on that figure. In both cases the mangrove absorbed less water than the wattle leather. The sum of the fixed tannin and total solubles is greater with the former than with the latter, and therefore there is less room for water in the mangrove leather, providing other conditions are equal for both leathers.

If t_1 is the percentage of water absorbed by a leather containing a small amount of water solubles, t_2 that absorbed by a leather with a large amount of solubles, and t_3 that absorbed by a rolled leather with a large amount of total solubles, then

$$t_1 = \frac{w}{r} 100;$$

$$t_2 = \frac{w - x}{r + y} 100;$$

$$t_3 = \frac{w - (x + m)}{r + y} 100,$$

where w = weight of water absorbed,
r = weight of leather,
x = water displaced by the extra amount of solubles,
y = weight of the extra amount of solubles,
m = the decrease in the volume of air spaces after the leather has been rolled.

Another factor would be an increased amount of insoluble matter such as combined tannin, bloom, and adulterants. Let t_4 be the percentage of water absorbed by a leather with a large amount of solubles and an excess of insoluble matter, then

$$t_4 = \frac{w - (x + l)}{r + y + u} 100,$$

where
l = water displaced by excess of insoluble matter,
u = weight of the excess of insoluble matter.

Water Penetration of Leather.

Leather, like wood, contracts or swells according to the moisture content, and this varies with the different tannages. The rate at which water penetrates the leather is related to the solubility of the substances deposited on the leather fibers. Leather adulterated with an easily soluble substance, like glucose, offers very little resistance to water penetration.

Tensile Strength Tests.

The tensile strength tests were carried out by Mr. H. T. Swain at the Mechanical Engineering Laboratory of the Sydney Technical College. Two pieces were cut from each section as shown on the diagram. Mangrove 4_a and wattle 8_a are placed together for comparative purposes, as they differ only in the barks used for the tanning process. The other groups are shown below, the results being all in favor of the wattle tannage.

Moisture Contents.

The moisture in the leathers is slightly higher with the wattle, and it is not possible to get the four sections with constant percentage of water when they are exposed to changeable climatic conditions. However, the difference is below 1%, and this amount will probably be reduced in future experiments.

The leather received no special treatment for this work, and was absolutely free from oil, fat, etc., other than the natural fats in the original hide. The pieces tested were not cut out of the best part of the hide and therefore the results obtained have no value outside of this experiment.

Analyses After Tanning.

Analyses show that these leathers differ after they are tanned, and therefore the results obtained may be influenced by this. The tensile strength of each section is at the maximum in the raw hide, where the physical condition is all that could be desired. A fibrous structure would be at its maximum tensile strength under conditions which allowed the weight to be evenly distributed between all the fibers. The other extreme would be under conditions where the whole of the weight was on a few fibers which break, and then the weight is thrown on another small portion which breaks also, and the result must be a low value for that particular test. It would not be possible to place all the weight on a few fibers until they break, if one were testing a strip of raw hide, where the elastic properties and the general structure are so finely balanced that a strain on any group of fibers causes them to stretch, and then the weight is partially taken up by other fibres, and in this way it is distributed over the whole number before any single fiber breaks. When the raw hide or pelt is placed in tannin solutions the physical condition is changed. It loses to a certain extent its elastic properties. The semi-liquid intercellular substances combine with tannin to form a non-elastic solid. The fibres contract and under certain conditions they may reach a brittle state.

Resistance to Friction.

Proctor states that the tensile strength decreases with increased amounts of fixed tannin, and the same could be said of those water-solubles which dry like tannin extracts to a hard brittle state. However, the variations in fixed tannin, etc., and their influence on these results is a problem which will require special research. If all other conditions were equal we would still expect a difference in tensile strength because the various tannins could combine with the hides in equal proportions by weight, and yet the resulting leathers would differ in their physical properties. The leather with the higher tensile strength will probably offer the greater resistance to friction. Balderston* has described a machine for testing the wear-resistance of sole-leather, and his results show that the loss by friction is at the minimum with a straight chrome and the maximum with a hemlock tannage. Now this is just the position one would expect them to occupy in a series of tests for tensile strength. Hard leather offers a low resistance to friction; the tensile strength is not high, but the water resistance is generally good.

We do not claim to be working the best processes for preparing the pelt or tanning the leather, but we feel certain that this "one hide experimental process" is capable of giving results which should enable tanners to prove the value of a great number of factors, such as various tanning materials, laying away in bark, acidity of liquors, strong liquors, time for tanning, etc.

CLOTHING FROM PEAT ON LARGE SCALE, IS REPORT

Interest is being manifested by American industrial chemists and manufacturers in a report regarding the economic utilization of peat fiber for clothing. An article referring to the new process appeared in "Textile Mercury," Manchester, England, from which it has been reprinted in the daily report of the U. S. Bureau of Foreign and Domestic Commerce as follows:

"A process is stated to have been perfected in Sweden for the manufacture of a strong textile material from peat fiber. The inventor, an engineer named Jegeäus, began to study this process twenty years ago, but was hampered by the fact that the manufacture was much too costly, so that he was unable to turn his ideas to any practical use. Induced by war conditions, however, he resumed his experiments, and has now succeeded in making dress materials from peat on a large scale.

---

*J. Amer. Leather Chem. Assoc., 1916, 11, 429. See J. Soc. of Chem. Ind., 1916, 935.

"The prices of these fabrics are said to be somewhat lower than those for artificial wool, and the durability great. The inventor himself and several other persons are already wearing 'peat' clothing, and a factory for the working of the process is about to be erected."

HIGH EXTRACTIONS FROM LEAD ORES OF LOW GRADE

New Method Resulting From Research Work at U. S. Bureau of Mines Experiment Station Has Many Advantages.

At the Salt Lake City, Utah, Experiment Station of the Bureau of Mines, Department of the Interior, Mr. A. E. Wells, metallurgist in charge, reported as follows to the Washington office of the bureau:

The most successful results of the metallurgical research branch during the month were with low-grade lead ores which have failed to yield to flotation or leaching processes described in previous reports. By mixing these ores with sodium chloride and heating to temperatures of about 800° C., high extractions can be obtained with the lead irrespective of the type of gangue in the ore. The lead volatilizes as a chloride and any silver or gold present is likewise volatilized. These chlorides are precipitated from the fume by the use of the Cottrell precipitator.

The precipitated lead chloride after a mixture with lime and a small amount of reducing agent is heated to a red heat, when a slag of calcium chloride and metallic lead is formed. The calcium chloride is an advantageous substitute for sodium chloride in the first operation and from 50 to 75° of the chlorine is recovered in this manner. This process will have the advantage of producing bullion from either oxides or sulphite ores in localities which do not contain sufficient water for milling purposes. Cost calculations indicate a considerable possibility of this process being cheaper than water concentration followed by smelting.

TENNIS STAR BECOMES INDUSTRIAL CHEMIST

R. L. Murray, Member of "First Ten," Enters Service of Hooper Company.

To those not already acquainted with the fact, the news that Robert Lindley Murray, one time Californian and now a resident of the East, is a chemist with the Hooker Electrochemical Co., manufacturers of caustic soda at Niagara Falls, N. Y., will be of considerable interest.

Murray, as all good tennis players know, occupies the fourth position in our national ranking—and to be fourth in that hallowed Hall of Tennis Fame known as the "First Ten," makes a man high among mortals for the rest of his life.

(Courtesy of "American Lawn Tennis.")
Robert Lindley Murray.

"Murray the Meteor" is his newspaper name, as McLoughlin's is "The California Comet"—but as Murray is slightly the "meatier" of the two—well, let it pass at that.

His serve, since becoming a full-fledged industrial chemist, blazes through the air like blue—vitriol and scorches the greensward when it hits, in fact so much so that the court is full of brown, seared spots after every match. Rumor hath it that there will be "no holding" Murray this year, for it has been reported (in strict confidence, of course) that he has succeeded in producing a synthetic catgut from cellulose which, when strung upon his racket, will impart to the flight of the ball a series of twists, curves and parabolas unparalleled in tennis annals. This, added to his blinding speed, is calculated to place him No. 1 in the 1917 ranking of tennis immortals.

THE DEVELOPMENT OF AMERICAN DYES

M. D. Reeser.

By Myron Drew Reeser*

An Appeal for Additional Government Support of the American Dye Industry Is Herein Made by Mr. Reeser, Who Declares That Today, Thanks to American Chemists, We Are Absolutely Independent of Germany So Far As the Necessary Basic Colors Are Concerned, and That With Proper Assistance During the Critical Period Following the War, American Manufacturers Can Place Themselves in a Position Where the Domestic Dye Market Can Never Again Be Dominated by Foreign Products.

IT is evident that this country is now facing one of the most crucial periods in its history. War encircles the world. In our hearts the hereditary spirit of patriotism is awakened. War is not a new experience to the American people. It is fraught with painful memories. Many a heart goes back in thought to the South where some loved one sleeps under the sod. Memories of other crucial periods are a stimulus to patriotic expression. Out of the battlefields of the South came the dawn of eternal brotherhood and unity. The price of war is devastation. Life, Art, Commerce are melted in the pot of hate. Out of the night is born the dawn of hope. Commercial activities are resumed. From blackened ruins huge structures are conceived. The sabre is forsaken for the plow. The minds of men, lately bent upon destruction, are united in construction.

Unity in construction is the vital point to be sought in the permanent establishment of any commercial effort. Not unity of mind conceived and born of war, but unity born of purpose. War has come. The greatest safeguard against war is preparedness. Competition is bound to come later. Germany will enter the color field, but never again will her iron hand hold this industry completely within its grasp. Since actual achievements prove that we are able to meet the color emergency, would it not be well to consider the following:

Secret of Germany Dye Supremacy.

What made Germany the dominating factor in the color industry? Was it those chemists who, over half a century ago, conceived the unlimited possibilities of the coal-tar industry with trained men, fostered by the government, money, laboratories and unlimited time at their disposal? Or was it the systematic development of many branches of the coal-tar industry of which colors formed only a part? All of these were bricks in the structure; but the secret was unity. Could such a unity of purpose ever be established in this country?

It is my firm belief that it could, and each month brings it nearer. Now that we have entered the war, would it not be well to forget all differences and to co-operate in commercial preparedness? It is safe to say that few if any chemists in the world could have done as much in such a short time, and under such trying circumstances as have American chemists. Today we are absolutely independent of Germany for the necessary basic colors and each month brings us new and encouraging developments. True, there are many of the more delicate shades yet to be perfected, but given one quarter of the time that was devoted to this industry in Europe, we will equal the world in range of colors and output.

Vast Potentialities in Coal-Tar Industry.

The American manufacturer of dyestuffs has profited by the war and the subsquent period of panic and trade cessation. Confidence influenced those men who spent millions in this industry, and confidence is the stabilizer of that industry today. War has come and for a time militarism will be the first consideration. But after the war we must turn to the generals who lead the armies of commerce. In the coal-tar industry and its subsequent development lie the possibilities of a great commercial unit. The demand for actual colors has been so urgent that many small plants have turned their efforts to this end when more attention to other branches might have been more advisable.

Recent developments in the photographic chemical field are indeed surprising. There seems, however, to be a desire for secrecy among the few companies entering this particular branch of the industry.

Closer Unity of Smaller Companies.

Perhaps this is wise, but each development, if immediately brought to the attention of those engaged in the coal-tar industry, is a means of strengthening the faith of consumers in the ability of American manufacturers.

There is not this hesitancy with regard to the larger manufacturers, as their products, when placed upon the market, must maintain the good name of the manufacturer.

---

*From The Dry Goods Guide.

This does not mean that there is a lack of co-operation between the large companies engaged in this industry, for that statement would be untrue.

A closer unity of the smaller companies is essential, for they lack sufficient funds to cope with the enormous expenditures necessary. It is a source of unlimited pleasure to converse with men who have led their organizations through the many difficulties attending the establishment of this industry. The lack of antagonistic feeling is surprising. Unlimited commendation is due them for their efforts in meeting the sudden demands of the textile and allied trades.

Today their plants are in a position to play a large part in the making of necessary war materials, such as high explosives, detonators, flame enveloping liquids and asphyxiating gases. They would undoubtedly be appealed to by the Red Cross for antiseptics, anæsthetics and pain-reducing drugs. The equipment of a large dyestuff manufacturing plant would be of more actual use, perhaps, than that of munition factories, for even though its total output might be less, its collective scope would be greater. If these large dyestuff manufacturers are ready to lend themselves to the government, why does the government fail to give them more assistance?

Government Can Help.

Foreign nations have always co-operated with those engaged in the coal-tar industry, and now in this reign of hate and strife we are told that disinfectants and hospital supplies are being turned out in enormous quantities by these plants. Our government would do well to emulate Germany in this respect. In conversation a few days ago, the statement was made that the American manufacturer of dyestuffs had not done enough to warrant protection by his government.

Much comment is heard regarding the attitude of certain well established chemical houses in jeopardizing the good will of their name through purchasing dyestuffs from doubtful manufacturers. There was apparently unlimited opportunity to make money, and this was undoubtedly the factor which led to their entering the color field. The promiscuous buying of dyestuffs regardless of circumstances is dangerous. This does not mean that the small manufacturer of colors is not reliable, but that the desire to accumulate wealth often overcomes the importance of establishing a name for quality and uniformity of their products. The output of colors today is very nearly equal to this country's total consumption. This output is controlled by companies which have established in past years a well deserved reputation. There are over one hundred coal-tar dyes now being produced in this country and the standard maintained is gratifying.

American Achievements Find Support.

The textile trade is unanimous in voicing its appreciation of the efforts of American manufacturers and is making contracts which should hold long after the termination of European hostilities. These American manufacturers are able to engage chemists from the large universities of the United States, and this assures the textile trade of uninterrupted service. A scholarship from these institutions is today on a par with any in Germany, and in most cases the strides in research work have been greater. The manufacturer of colors is placing his faith in the efforts of these younger men to carry on the industry, and that faith is assuredly well placed.

German dyestuff manufacturers have a capital of one hundred million dollars and German dye-making plants were for the most part free to debt. They had forty years of technical experience and unlimited scientific laboratories at their disposal. Germany also had one of the most wonderful and far-reaching selling organizations ever conceived. Today the American chemist is protected by ample capital for experimental expenditure. His training has been more rapid because of necessity. He will have back of him an American selling organization and the actual experiences of foreign representatives. The American manufacturer will broaden his field of operation and even now representatives are being placed in foreign cities.

Opportunities for Chemists Unlimited.

The field of opportunities presented to the young chemist is unlimited. The serious circumstances which confronted those engaged in this industry before the war are no longer a hindrance, for now this country is producing more raw materials than could be consumed in normal times. By this is meant the principal raw materials, such as toluol, benzol napthaline and kylol. When the need of other materials is urgent there is no doubt that American manufacturers will meet the demand. The raw material question has been solved and never again will it stand in the way of development.

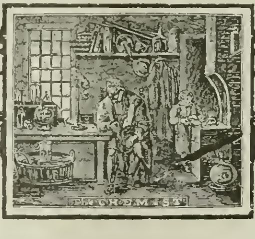
There has been a ready spirit of co-operation manifested by the maker of machinery, and judging from his efforts one can safely say that he has ability to a surprising degree. Raw materials, brains, money, equipment, all of these are at the disposal of this industry, and with governmental protection added, the ultimate result would be more readily attained. Certainly the government has helped, but an industry so vital to the commercial prosperity of this country needs still further government backing.

MARKET DESIRED FOR MANGANESE ORE.

An American consular officer in South Africa has transmitted the name and address of a person who desires to get in touch with consumers of iron ore in the United States, as he desires to market 500 to 1,000 tons of this product. The person's name can be obtained at the Bureau of Foreign and Domestic Commerce or its district or co-operative offices by referring to file No. 85343.

CHEMICAL INVESTIGATION
EFFICIENCY & CONTROL

CONDUCTED BY CHARLES B. DAVIS, F.C.S.



ALL classes of work covered by the following subjects will be done for readers of "The Chemical Engineer" through this department by Mr. Davis: Special research of every description; analysis and reproduction of any commercial product; prevention of waste and utilization of by-products on the most economical basis; valuation of raw materials; food analysis, and disputed points in regard to adulteration, labeling, and the enforcement of pure food laws; bacteriological and enzymatic examinations, including fermentation tests, pure yeast cultures, beverages of all kinds; development of chemical inventions and industrial processes; examinations and advice on special machinery.

Inquiries of a minor character will be answered on this page, while major matters involving personal investigations, analyses, etc., will, if desired, be treated confidentially through the mails. All questions, materials for analysis, or letters leading to the opening of negotiations for special work will receive prompt attention if addressed to

CHARLES B. DAVIS,
Care of "The Chemical Engineer," 118 East 28th Street,
New York City.

J. T. T. Fertilizers are now sold on specified and guaranteed analyses. If your products do not come up to these standards they will be returned. I would advise you to have an analysis made of each batch before sending it into the trade. (41)

C. G. For the determination of sulphur and phosphorus in your steel samples, only borings should be forwarded. Six or eight ounces will be required for the tests.

P. H. It is very necessary to determine the water content of sulphurated cod liver oil, which is used in the manufacture of leather, as much of it contains upward of 30 per cent. In sending samples for analysis forward about four ounces. (2) This subject is covered fully in another part of this issue of "The Chemical Engineer."

A. T. By stating for what purpose the sample is intended much time and expense will be saved.

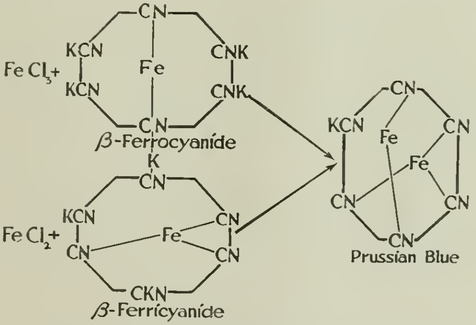
E. E. S. All samples for chemical analysis or analysis and working formulas, as well as research work in general, should be addressed to Charles B. Davis, care of The Chemical Engineer, 118 East 28th Street, New York.

B. A. B. It is a fact that many dyes were brought over on the Deutschland, but no shortage is to be felt in the future for these products, since our own chemists are now turning them out in large quantities. (43)

A. H. A water used for your special process should have a composition suitable for its purpose. If the supply on hand does not meet these requirements, it can be softened or hardened as the case may be and made fit. A gallon sample will be required for the analysis. (50)

P. A. F. If you are uncertain as to the quantity of sodium benzonate your tomato stock contains it will be well to send a four oz. sample for the exact determination of this preservative, as ½ of 1% is the amount now allowed. (48)

A. A. T.—Your request for the latest chemical formula of Prussian Blue has been looked into very carefully, and is as follows:



S. C. B. Angostura bitters contains from 15 to 20 ingredients, and will require a week or so for its complete analysis. A working formula can be supplied for this or any other commercial product you may wish examined. (36)

C. K. Temperance drinks are either non-alcoholic or contain not more than 2 per cent. alcohol, according to the laws of the various states. If you will tell me into which state or states your particular drink is to be shipped I can furnish the exact strength of alcohol allowed. (47)

D. D. When sending the machine and cylinder oils your mention in your last letter kindly forward pint samples, as small quantities will not allow of complete analyses. (26)

T. M. If your paint does not dry it may be due to too high boiling point solvent or too much water. These defects can be detected easily, at small cost, by chemical analyses. (33)

Charles B. Davis

DISTILLATES

News Notes of Chemical and Allied Industries

Missouri-Arkansas Oxygen Co. Created.

With a capital stock of $25,000, the Missouri-Arkansas Oxygen Co., of St. Louis, has been incorporated by Rudolph Best, Oscar G. Reichardt, Louis Rosen and several others.

Will Develop Graphite Properties.

For the development of graphite properties near Pyriton, Ala., The Great Southern Graphite Company will maintain a plant with a daily capacity of 300 tons.

Anhydrous and Aqua Ammonia.

With a capital stock of $650,000, the Alcohol Products Co., of Newark, N. J., has been incorporated under the laws of that state to manufacture anhydrous and aqua ammonia, and chemicals, by H. T. Edgar, H. M. Miner, Brooklyn, and H. W. Haines, Millburn.

Compressed Gasoline Oils.

A process of compressing gasoline oils from casing and head gas will be undertaken by Gasoline Producing Corporation, Wilmington, Del., which has recently been incorporated with a capital of $1,000,000.

New Offices for National Aniline.

Application to establish offices in Charlotte, N. C., has been filed by the National Aniline and Chemical Company, of New York City.

Bronzo Alumina Corporation.

Aluminum, silicon, bronze and iron castings will be dealt in by the Bronzo Alumina Corporation, of Tonawanda, New York, which has recently been incorporated with a capital of $16,000 by F. A. Redner, J. E. Kaufman and J. H. Willing, 141 Masten Street, Buffalo.

De Vore Chemical Company.

Chemicals will be manufactured by The De Vore Chemical Company, Columbus, Ohio, which has been incorporated with a capital of $50,000 by P. R. De Vore, P. F. Wilkinson, C. E. Williams, W. C. Shacklett and J. E. Waddy.

New Paint Manufacturers.

Paints, stains, etc., will be manufactured by the Mansfield Paint Company, Mansfield, Pa., the incorporation of which with a capital of $150,000 has been announced. The incorporators are C. H. Rane, Mansfield, Pa.; D. D. Buck, George W. Dillman, all of Wilmington, Del.

Sunbeam Chemical Company.

The Sunbeam Chemical Company, of Chicago, has been incorporated under the laws of Illinois with a capital stock of $25,000.

French Perfume Increases Stock.

An increase in its capital stock of from $20,000 to $30,000 has been made by the French Perfume, Medicinal and Aniline Manufacturing Company, Inc., of New York.

Chemechlec Company Incorporated.

The Chemechlec Company, of Camden, N. J., has been incorporated under the laws of that state by Frank A. Lane, Frank A. Rowcroft and H. Lindsay Vogel.

To Build Coke Oven.

Plans are being discussed by the Monongahela Traction Company, of Fairmount, West Virginia, to build a by-product coke oven in that state.

Fuller's Earth Company Organized.

The Medina Fuller's Earth Company, of San Antonio, Texas, has been incorporated with a capital stock of $100,000 by O. T. Gregory and E. D. Henry, of that city, and L. R. Parker, Aurora, Ill.

Dyestuffs, Paints and Drugs.

The K. F. G. Products Company, New York, has been incorporated with a capital of $10,000 to deal in chemicals, dyestuffs, ores, compounds, paints and drugs. The incorporators are S. Greenberg, I. Lowenbraun and B. L. Karliner, 116 Nassau Street.

Petroleum Light and Heat Co.

Petroleum will be manufactured and produced by the recently incorporated Petroleum Light and Heat Company, Wilmington, Del. The capital of the new concern is $50,000, and the incorporators are M. L. Rogers, L. A. Irwin and H. W. Davis, all of Wilmington, Del.

Gas, Oil, Etc.

Empire Refineries, Inc., Augusta, Maine, has been incorporated with a capital of $5,000,000 to deal in gas, oil and other mineral bearing properties.

Chemists and Chemical Manufacturers.

Pittsburg-Utah Potash Fertilizer Company, Wilmington, Del., has been incorporated with a capital of $500,000 to carry on the business of chemists and chemical manufacturers. The incorporators are F. D. Buck, George W. Dillman and M. L. Horty, local Wilmington incorporators.

FOREIGN TRADE OPPORTUNITIES

These Opportunities for Foreign Business Relations Are Made Public by the Bureau of Foreign and Domestic Commerce, of the Department of Commerce, Washington, D. C. Names, Addresses and Details May Be Obtained Directly From the Bureau or Any of Its Branches. Refer to the Number of Each Opportunity and Place Inquiries for More than One on Separate Sheets.

Brewery Supplies.

23982.—A representative of American firms in France, with an office in the United States, desires to be placed in communication with American manufacturers and exporters of brewery supplies and machinery. References.

Cattle Hides; Sugar; Cereals.

23949.—A man in Spain desires to be placed in communication with American manufacturers and exporters of cattle hides for furniture, carriages, boots and shoes, etc.; codfish, sugar, cereals, and sausage casings. Correspondence may be in English.

Copper Sulphate.

24122—A man in France is in the market for large quantities of sulphate of copper for spraying vineyards. Quotations should be made c. i. f. Bordeaux, if possible. References. Correspondence should be in French.

Copper Sulphate.

23930.—A firm in Spain desires to purchase sulphate of copper, 98/99 per cent. Quotations should be made c. i. f. destination. Cash will be paid. Goods should be put up in barrels. Correspondence may be in English. Reference.

Analyzed Granulated Sugar.

23947.—A merchant in Italy is in the market for best quality granulated sugar in weekly consignments. Analysis of the sugar is required. Quotations should be made c. i. f. Genoa. Payment will be made by cash against shipping documents. Correspondence may be in English. References.

Cement Mosaic Colors.

23936.—A manufacturer in Spain is in the market for colors used in the manufacture of hydraulic cement mosaic. Quotations should be made c. i. f. destination. The material should be packed in small barrels. Correspondence should be in French or Spanish. References.

Cotton; Rosin; Caustic Soda.

23988.—A company in Brazil desires to secure an agency for the sale of cotton, rosin, and caustic soda. Correspondence should be in Portuguese or Spanish. References.

Bicarbonate of Soda.

24114—A man in Canada desires to purchase bicarbonate of soda in kegs, barrels, and casks, in carload lots, or secure an agency for the sale of same. Quotations should be made f. o. b. shipping point. Goods should be shipped c. o. d. Correspondence may be English. Reference.

Tanning Extracts.

24101—A firm in Spain wishes to secure an agency for the sale of tanning extracts. Quotations should be made c. i. f. destination. Correspondence should be in Spanish or French. References.

Indigo Bluing.

23934.—A man in Spain wishes to secure an agency for the sale of indigo bluing. Quotations should be made c. i. f. destination or Barcelona. Payment will be made against shipping documents in Spain. Correspondence may be in English. References.

Caustic Soda.

24031.—A firm in Switzerland is in the market for 66,138 to 110,230 pounds of caustic soda 125 degrees. Quotations should be made c. i. f. Genoa. Payment will be made against shipping documents. The soda should be put up in air-tight, soldered, sheet-metal drums of 661 to 881 pounds. Correspondence should be in German. References.

Sphygmomanometers.

24037.—A doctor in a French insular possession desires to purchase sphygmomanometers. He also wishes to receive catalogues from American manufacturers and exporters of surgical instruments and physiological apparatus. Cash will be paid. Correspondence may be in English, but French or German-French is preferred.

Scientific Apparatus.

23966.—A firm in Spain desires to buy scientific apparatus, such as drawing instruments, metric measures and scales, surveying instruments, calculating slide rules, thermometers and barometers, telescopes, microscopes, and chemical balances and weights, or secure an exclusive agency for the sale of same. Correspondence may be in English. Reference.

Soap Ingredients.

23957.—A firm in Argentina desires to purchase bright galvanized corrugated iron sheets of good quality, 8/3 by 24 gauge, in 6 to 10 foot lengths. The firm also wishes to represent American manufacturers and exporters of pitch pine, rosin, and ingredients for the manufacture of soap, such as caustic soda, soda ash, silicate of soda, bicarbonate of soda, chloride of lime, soda crystal, and cocoa oil. Quotations should be made c. i. f. destination. Payment will be made by cash against documents through local bank. The galvanized sheets should be packed in skeleton felted cases. Correspondence may be in English. Reference.

THE CHEMICAL ENGINEER

VOL. XXV. MAY, 1917 No. 3

Published Monthly by the

McCready Publishing Company.

ROBERT H. McCREADY, President
DAVID R. PERAZZO, Treasurer
118 East 28th Street, New York

LAURANCE T. CLARK, Editor
CHARLES B. DAVIS, F. C. S., Consulting Editor

Entered as Second Class Matter at the Post Office at New York, N. Y., under the Act of March 3d, 1879.

Subscription—United States, Cuba and Mexico, $2.00; Canada, $2.50; other countries, $3.00.

Single Copies, 25c.

Statement of the Ownership, Management, etc., Required by the Act of Congress of August 24, 1912,

Of the Chemical Engineer, published monthly at New York, N. Y., for April 1st, 1917.

County of New York, State of New York, ss.

Before me, a Notary Public in and for the state and county aforesaid, personally appeared Robert H. McCready, who, having been duly sworn according to law, deposes and says that he is the Business Manager of the Chemical Engineer, and that the following is, to the best of his knowledge and belief, a true statement of the ownership. management (and if a daily paper, the circulation), etc., of the aforesaid publication for the date shown in the above caption, required by the Act of August 24, 1912, embodied in Section 443, Postal Laws and Regulations, printed on the reverse of this form, to wit:

1. That the names and addresses of the publisher, editor, managing editor, and business managers are: Publisher, McCready Publishing Co., 118 East 28th St., N. Y.; editor, L. T. Clark, 118 East 28th St., N. Y.; managing editor, none; business manager, R. H. McCready, 118 East 28th St., N. Y.

2. That the owners are: C. J. O'Brien, 22 North William St., N. Y.

3. That the known bondholders, mortgagees, and other security holders owning or holding 1 per cent. or more of total amount of bonds, mortgages, or other securities are: None.

4. That the two paragraphs next above, giving the names of the owners, stockholders, and security holders, if any, contain not only the list of stockholders and security holders as they appear upon the books of the company but also, in cases where the stockholder or security holder appears upon the books of the company as trustee or in any other fiduciary relation, the name of the person or corporation for whom such trustee is acting is given; also that the said two paragraphs contain statements embracing affiant's full knowledge and belief as to the circumstances and conditions under which stockholders and security holders who do not appear upon the books of the company as trustees hold stock and securities in a capacity other than that of a bona fide owner; and this affiant has no reason to believe that any other person, association, or corporation has any interest direct or indirect in the said stock, bonds, or other securities than as so stated by him.

ROBERT H. McCREADY.

Sworn to and subscribed before me this 30th day of March, 1917.

FREDERICK PFISTER.

(My commission expires March 30, 1917.)

See Announcement on Opposite Page.

DR. THOMAS H. NORTON TO EDIT DYE DEPARTMENT FOR THE CHEMICAL ENGINEER

In the history of American manufacturing industries there is nothing comparable, in rapidity of evolution, with the American coal-tar chemical industry.

In all its manifold ramifications, from the production of crude materials, the refining of these crudes and their transformation into intermediates, to the manufacture of a large variety of staple dyestuffs, synthetic medicinals, photographic chemicals, etc., and the production of vast masses of high explosives, this young industry has suddenly emerged from its swaddling clothes and quickly sprung to man's stature.

There is a strongly expressed opinion on the part of many identfiied with this industry that the time has arrived for it to possess its own organ—a journal in which its interests will be fully represented and defended.

To meet this legitimaate demand, the publisher of the Chemical Engineer has decided to devote a large share of its space to a department occupied exclusively with coal-tar chemistry. Every phase of the industry, scientific, technical and commercial, will receive full and adequate treatment. The needs of producers and consumers will be studied with equal care. Coal-tar colors will necessarily be a dominant feature, but consideration will be given to the so closely allied natural dyestuffs. No pains will be spared to make this department fully equal in practical value to the British, French and German periodicals devoted to the interests of makers and users of artificial and vegetable colors. Special attention will be given to the mechanical phases of the problem, to all devices simplifying and standardizing the production of coal-tar crudes, intermediates and finished colors, or other synthetic products, as well as the use of coal-tar compounds in dyeing and in the arts generally.

The publisher of the Chemical Engineer takes pleasure in announcing that he has secured as editor of this department Dr. Thomas H. Norton, who has labored so actively during the past two years under the auspices of the Department of Commerce to stimulate, aid and further the expansion of this new national industry.

Dr. Norton will be assisted by a corps of Associate Editors, including several prominently identified with the building up of the American coal-tar chemical and color industry, and others equally prominent among the consumers of its products. The co-operation of able foreign correspondents has also been assured.

To members of the chemical fraternity in general, and to all who are connected with the production of dyestuffs both here and abroad, Dr. Norton needs no introduction.

As a special agent of the Bureau of Foreign and Domestic Commerce, at Washington, and author of the complete census of artificial colors used in this country entitled "Artificial Dyestuffs Used in the United States," his work has attracted international attention. He is an investigator of unusual experience and an author of repute on chemical and industrial topics. He has published a great number of papers containing the results of his researches in mineral, organic and technical chemistry. Among the books from his pen are:—"The Application of Aniline Colors to the Dyeing of Leather," 1877; "Chemical Exhibits of the Paris International Exposition of 1878"; "The Utilization of Atmospheric Nitrogen," 1913, regularly used as a textbook both here and abroad. "The Chemical Industries of Belgium, Holland, Norway and Sweden," 1913, translated into German; "Dyestuffs for American Chemical and Other Industries," 1915; "Cottonseed Industry in Foreign Countries," 1915; "The Dyestuff Situation," 1915; "Potash Production in California," 1915; "Potash from Kelp," 1915; "The Dyestuff Situation," January, 1916—second edition, May, 1916.

Dr. Norton was born in Rushford, N. Y., June 30, 1851, and was graduated at Hamilton College in 1873 as valedictorian, and first prize man in classics, mathematics, chemistry and physics. He studied at the University of Heidelberg under Bunsen and Kirchoff in 1873-1875, and won his Ph. D. there. He was a student at the University of Berlin in 1876-1877 with August Von Hofmann, in whose laboratory the first aniline color was discovered, and was a student at the University of Paris in 1877-1878. During these years he made journeys on foot of more than 12,000 miles in Europe and Western Asia, and was the first to traverse Greece, Palestine and Syria on foot alone.

For five years, from 1878 to 1883, he was manager of the chemical works of the Compagnie Generale des Cyanures of St. Denis, near Paris, manufacturing dyeing materials. Returning to this country he was for 17 years professor of chemistry at the University of Cincinnati, 1883-1900. In the latter year he was appointed by President McKinley to establish an American consulate at Harput, Eastern Turkey. During 1904 Dr. Norton engaged in a special investigation of the Armenian situation, and in the winter of 1904-1905 he was sent on a diplomatic mission to Persia by President Roosevelt. In 1905-1906 he was American consul at Smyrna, and from 1906 to 1914 American consul at Chemitz, Saxony. Here he was largely occupied with textile problems in connection with the application of colors to fabrics. In 1911-1912 he was detailed on special service for the Department of Commerce to study the chemical industries of Europe. The results of his investigations are found among the special monographs already mentioned.

THE POTASH "NOOSE"

By THOMAS H. NORTON, Ph. D., Sc. D.

Despite the Gloomy Predictions of One of Germany's Leading Chemists, There Is Not, Dr. Norton Hastens to Assure Us, the Slightest Danger of the Threatened "Strangulation" of Our Food Production Through Inability to Utilize Our Great Natural Sources of Potash. In the Following Article He Describes Where Our Supply Lies, and What Has Been Done to Make It Available.

DURING the first week of May, 1917, Professor Wilhelm Ostwald, of Leipzig, who stands in the very fore-front of Germany's chemists and even philosophers, published the following statement:—

"America went into this war like a man with a rope around his neck, which is in the enemy's hands and is already pretty tightly drawn. With its tremendous deposits Germany has a world monopoly in potash, a point of immense value which cannot be reckoned too highly when once this war is going to be settled. It is in Germany's power to dictate which of the nations shall have plenty of food and which shall starve."

I have a profound respect for Professor Ostwald's scientific attainments, and for his rank as a clear, logical thinker. Yet it is impossible to read the above without seeing in the statement another of the striking examples, so frequent during the past three years, of the apparent inability of highly trained Teutonic minds to correctly appreciate the spiritual and the material resources lying either half hidden or dormant in other races and other lands.

For years the German chemist has firmly maintained the thesis that the magnificent and almost unique deposits of Stassfurt are the sole practical source of potash to meet the world's needs in agriculture and in the arts.

If he grants that potash is widely diffused in the mineral and vegetable kingdoms, he asserts at the same time that it is beyond the possibilities of chemical technology to separate and secure it, in commercial forms, and at costs of production which will ever threaten the dominance of the Stassfurt output. Professor Ostwald's latest utterances would indicate even a disbelief in the ability of foreign chemists to recover potash in adequate amounts, on an industrial scale, quite apart from the cost of production.

It would certainly appear as if our fellow chemists in Germany are totally unaware of the wealth of potash, in this country alone, and of the marvellous efforts being exerted to render it available for the nation's needs during the past two years.

Let us note just how near we are to strangulation from the "noose" of Professor Ostwald's figure, what danger we are actually incurring from the interruption in our customary supplies of potash salts from the Stassfurt mines.

If we were using potash in American agriculture as generously and sensibly as is the rule in Germany and in adjacent countries, notably in Belgium, Holland and Denmark, Professor Ostwald's reasonings would rest upon a better basis. Unfortunately this is not the case. We are only beginning to appreciate the importance of ample rations of potash, phosphoric acid and nitrogen for our growing crops. The American farmer is content to harvest 15 bushels of wheat per acre, while the Dane or German secures double or triple this amount for the same amount of labor.

American agriculture should consume ten times the quantity of potash currently employed prior to the war. The consumption at that time was very unevenly distributed. Thus, the amount of potash per 100 acres of cultivated land regularly used in Florida was 2,131 lbs. In Illinois it was but 12 lbs. In Kansas it was but half a pound.

All told, American farmers were using about 1,000,000 tons of potash salts yearly, and varied industries, notably glass and soap manufacture, required in addition, about 23,000 tons.

Since March, 1915, there has been a genuine "potash famine" in this country, attended by the inevitable dislocation of technical and commercial organization resultant upon a sudden shortage in the supply of a staple article.

The emergency called for prompt and radical action. In a general way it was known that our vast domain contained enormous amounts of potash—present nowhere in such abundance as at Stassfurt—but still in such quantities that the possibility of economic utilization under normal conditions was a farly debatable question.

When quotations for potassium compounds increased to ten-fold the customary rates, American enterprise needed no further stimulus. The problem was promptly tackled from a number of points.

The actual results obtained during 1916 show clearly that this country is destined to have its own potash industry, meeting completely the nation's varied needs, and that at no distant date.

The various phases of the solution of the potash situation may be briefly enumerated.

First and foremost comes the utilization of the enormous amounts of the compound stored annually in the kelp crop of our Pacific littoral. The possible yearly harvest has a value estimated at from $50,000,000 to $90,000,000 as prices ruled in 1913. If it be used as a fertilizer the nitrogen content means an additional increase in value of $30,000,000 to $60,000,000. There is no need of plowing, sowing or cultivating. Nature does it all. Harvesting by means of an aquatic reaper and mower is the sole operation involved. The gathered product, dried and ground, is ready for use as a fertilizer. It can easily compete in the cotton fields of the South and in the varied agriculture of the Atlantic states, with the potash brought from Germany.

A score of factories are now busily engaged in this new industry, located largely along the southern coast of California, but to some extent about Puget Sound.

Much of the product is prepared for direct use as a fertilizer. Some serves as raw material for the extraction of potassium salts to be used in the arts, following the practice along the coasts of Brittany, Norway, Scotland and Japan.

It is the beginning of a grand exploitation of one of the nation's most valuable assets, one which is renewed every year, and not destined to ultimate exhaustion and disappearance, as is the case with our coal veins, the deposits of Chile saltpeter or the mineral occurrences of potash.

The seaweed or kelp of the Atlantic contains a materially lower percentage of potash than is the case with the varieties found in the Pacific. Still the amount present is of great value during the temporary era of abnormal prices. The vast mass of seaweed in the central Atlantic, known as the Sargasso Sea, offers the most tempting field for operations. A campaign is now under way, directed from the Florida coast, for the systematic exploitation of this great bed. A huge barge of concrete is towed to the distant location, with supplies for a year's operations. With the help of auxiliary small craft the kelp is collected and the processes of desiccation and extraction are effected upon the barge, from which the concentrated products are shipped from time to time to American ports adjacent to fertilizer centers. The whole plan is of great interest, combining simplicity, low cost of production and a notable magnitude of operation.

A considerable amount of potash, of a different vegetable origin, has hitherto gone to waste in distilleries using molasses, as a raw material, for fermentation. There are twenty-six such distilleries in the United States and the daily waste has averaged 106 tons of pure potash (K_2O). A process has now been perfected for the complete recovery of this amount in a perfectly dry form, admirably adapted to the needs of the manufacturers of composite fertilizers.

Potash is now recovered as a by-product, in connection with our iron industry. Certain varieties of our Alabama ores contain over 3% of potash. A large proportion of the volatile salts escapes in the waste gases of the blast furnace, and is now systematically collected.

A similar source is encountered in connection with the manufacture of cement from limestones and clays containing appreciable amounts of the alkali. Over one half of the quantity present escapes in the stack gases.

In both cases the Cottrell electrical precipitation process is used with great success in isolating the potash fume from the current of waste gas. It is evident that this clever, but exceedingly simple process is destined to play an important role in establishing upon a firm basis the American potash industry.*

One leading line of active investigation includes the many efforts devoted to solving the problem of an economical extraction of the potash present in feldspar. Our supplies of the mineral are inexhaustible, and the potash content often ranges from 10 to 14 per cent. Thus far marked success has not attended the attempts in this field.

Some promising methods are emerging from the experimental stage, in which alumina is recovered simultaneously with potash. The utilization of feldspar in cement manufacture offers apparently the best chances of success under normal conditions. An essential feature is an ample supply of aluminiferous limestone to counter-balance the low percentage of alumina in feldspar.

Much more pronounced success has attended the efforts undertaken to economically utilize the nation's magnificent asset in the vast alunite deposits at Marysvale, Utah. The calcination process was first introduced in the autumn of 1915. Since then large amounts of potassium sulphate of a high technical quality have been regularly shipped to eastern points.

During 1916 the process based upon the use of nitric acid for the direct treatment of the rock has been introduced and shows itself to be an economic success. There is no evolution of acid fumes as in the calcination process. All of the potash present is obtained directly as potassium nitrate (saltpeter) of a high degree of purity. It can be employed directly in the manufacture of explosives and otherwise in the arts, or transformed into the many different potassium salts, for which there is so extended a demand, with a nearly complete recovery of nitric acid. The alumina present is likewise secured in a state of high purity, admirably adapted for use in the manufacture of metallic aluminum as well as in the manufacture of aluminum sulphate, the alums, etc.

---

*It is of interest in this connection to note that a large factory in California, which is using the process in question, has temporarily suspended its output of cement, on account of market conditions, but is still running its kilns in order to recover all available potash, and storing up the clinkers.

The process is a distinct contribution to our stock of technical operations in this field of chemical technology and seems destined to enable us easily to compete, under normal conditions, with Stassfurt as a source for the staple potash products required to such a vast extent in the arts. There is a possibility that in the cruder, least expensive forms, the saltpeter obtained primarily may play an important role in supplying a highly concentrated constituent of plant food for use in preparing artificial fertilizers to be transported long distances.

The recovery of potash salts from the highly concentrated brines or bitterns of various inland springs and lakes in the western section of the country is steadily attaining a notable degree of perfection. Shipments from Owens Lake and Searles Lake, California, have become a commercial factor. A large amount of capital has been invested at the latter point.

Another source of interest is the separation of potassium chloride from the mother liquors resultant from the extraction of salt from sea water on the California coast. The process gives every evidence of being a financial success.

Altogether those keenly following the evolution of a genuinely American potash industry have every reason to be satisfied with the giant strides made during 1916, in advancing rapidly toward the goal in view. Processes have reached such a state of perfection that the problem is now rapidly becoming one of a geographical nature, in which the rates of transportation between points of production and regions of consumption become dominant factors. The time requisite for the multiplication of factory units must also be taken into consideration.

The annual consumption of potash compounds in the United States, immediately prior to the world's war, was, as stated above, somewhat in excess of 1,000,000 short tons. The plant necessary for such an output will necessarily require several years in construction.

We can, however, look confidently forward to an early date in the future, when our American potash industry will be standardized, when the equilibrium between the varying costs of production in connection with the numerous sources mentioned above, and the miles of widely separated sections of our land, will be fairly well adjusted, when the fleet of steamers ordinarily transporting potash salts to our shore will be diverted to other purposes, and finally when American potash will seek an output in Latin America, across the Pacific and possibly even in Europe.

Of the "strangulation," the starvation, threatened by Professor Ostwald, there is not the slightest danger!

THE INDUSTRIAL CHEMIST AND THE FERTILIZER CRISIS.

By H. Clay Lint, Ph. D.*

Without Attempting to Disguise the Seriousness of the Situation Which This Country Will Be Called Upon to Face as Regards Nitrogen, Phosphorus and Potash for Fertilizers, the Author Herein Considers the Problem from the Standpoint of the Industrial Chemist, and Discusses Peat and Muck as a Source of Organic Ammoniates.

PERHAPS at no time in its comparatively brief history has the fertilizer industry been confronted with more serious problems. In seeking the reason for this situation by studying every item which helps to maintain the unstable commercial fertilizer equilibrium, we arrive at the same causative factor—war.

This industry draws the raw materials from which its finished products are prepared from all corners of the globe, and with practically all of these various corners embroiled in war, it is only natural that great difficulties should be encountered. Like the curing of any disease, whether personal or commercial, there exist but two methods of cure: the removal of the cause, or the finding of a remedy. In the present case, the removal of the cause is an impossibility, so that our efforts must necessarily focus upon remedial measures.

The chemistry of the fertilizer manufacturer includes but three elements; Nitrogen, Potash and Phosphorus. When the handling, however, reaches into the millions of tons, the small number of elements concerned assume a mien of greatest importance.

Thanks to wide newspaper comment, it is now common knowledge to the layman that practically all of our potash supply came from Germany. Chemists were quick to realize the necessity for prompt action in producing potash salts from domestic sources the moment overseas shipment from Germany ceased. To date, the chief sources of supply for domestic potash, according to the latest report of the United States Geological Survey, have been as follows:

---

*Research Chemist and Bacteriologist, Alphano Humus Co., 17 Battery Place, New York City.

Some Domestic Sources of Potash.

Mineral Sources: Natural Salts and Brines, 3,850 tons. Alunite and Silicate Rocks, including furnace dust recoveries, 1,900 tons; making a total derived from mineral substance of 5,750 tons. The data are for the 1916 output, which in value is ten times that of 1915, showing to what extent the production increased during the last year. Allowing for unreported sources, there were about 10,000 tons of K_2O produced, valued at $3,500,000.

From organic sources, 1,110 tons came from kelp. Twenty-three out of a total of seventy producers report a total tonnage of 220 derived from Wood Ashes. Miscellaneous industrial wastes contributed 1,750 tons, making a total from organic sources of 3,080 tons. The greater part of the mineral supply was obtained from the Nebraska alkali lakes. Late reports show that the large modern plant of the Pacific Coast Borax and the Solvay Process companies situated at Searles Lake in California are ready to start operation. The output from this place is estimated at 1,000 tons per month, which in itself practically equals the production of last year from all sources.

The most generous estimate for the 1917 production, however, does not measure up to the huge industrial and agricultural demand for potash, so that while an admirable start has been made, still the potash problem may be looked upon as unsolved.

A Nut for the Chemist to Crack.

The one big, almost inexhaustible supply of potash in this country lies in Orthoclase, or Potash Feldspar. To render this potash available, and at a cost that would make the process commercially profitable, is one of the problems that the industrial chemist has yet to solve. It is true that a great amount of work has been done, but none of the processes are above objection. It appears *a priori* that in some way this can be accomplished, and that orthoclase potash can be put on as big a commercial basis as the acid phosphate industry.

Industrial waste products can undoubtedly be made to yield a richer return in potash fertilizers as a result of improved methods to be worked out by the industrial chemist. Here again the limiting factor of costs is the shackle that must be broken in many instances. A better conservation and possible concentration of wood ash might easily make this source of supply of greater importance, but such work is more a matter of engineering than of chemistry. Converting the insoluble potash of wood ash into available form is a chemical phase of any wood ash work to be considered.

The close sighted layman sees no excuse for phosphorus shortage when told of our wonderful resources of this material. He fails to appreciate the vital importance of acidulation, and it is this chemical phase of production that has made the situation acute. The chief factor is that of interrupted commerce, and the traffic manager may be a more important person than the chemist as far as phosphoric acid is concerned.

Transportation Presents Serious Problem.

Coastwise traffic is greatly curtailed, due to the diverting of vessels to European channels. Rail transportation has necessarily increased to European channels. Car shortages all over the country have made the moving of materials most difficult. This is particularly so because of the present imperfect service of the Southern railroads, over which practically all phosphate rock must move.

A transportation factor that is influencing a more strictly chemical phase is that of a practical stoppage of the importation of Iron Pyrites from Spain.

This means that many of the big acid plants will be forced to remodel in order that they can use elemental sulphur. The enormous demand for sulphuric acid in the manufacture of munitions has practically doubled the cost of this article, so that we see a second legitimate reason why the cost of acid phosphate should be increased.

Raw rock phosphate has quite generally given less profitable results than those obtained from the acidulated material, and the difficulty cannot be eliminated by so happy a suggestion as the use of raw rock. Dr. Lipman, of the New Jersey Agricultural Experiment Station, has worked out a composting method, whereby sulphur, acidized by bacteria, forms sulphuric acid in the soil. By having this action take place in the presence of phosphate rock, the material is made available. About 60 per cent. to 75 per cent. of the total phosphorus is utilized

Considering the nitrogen conservation, the method recommends itself under many conditions. Many florists and truck gardeners annually prepare their compost piles, and where facilities are available, it is practical for farmers to add the proper amount of sulphur and floats to animal manure. Five parts of sulphur, fifteen parts of floats were added to one hundred parts of soil in the work reported by Lipman.

U. S. Must Face Nitrogen Situation.

The situation as regards nitrogen is fully as serious as that of potash. Imports of sulphate of ammonia and cyananid from Europe are practically cut off. Scarcity of ships for bringing nitrate of soda from Chili has greatly curtailed the importation of this material and forced a corresponding rise in the price. The fuller utilization of animal matteby the packers for foodstuffs has cut down on production, but the more serious aspect of the shortage has been brought about through the increased usage of organic ammoniates for animal feeding purposes. At present, any animal ammoniate is worth practically $5.00 a unit—with none on the market even at that price. Garbage tankage, which only a few years ago was considered greatly inferior, is now costing over $4.00 a unit, and the supply is short of the demand.

Great seriousness is attached to the organic ammoniate problem, because of the fact that the delectable status quo ante bellum will not be re-established by the treaty of peace. In fact, it can almost be stated that the day has passed altogether for the utilization of high grade animal tankages by the fertilizer industry.

Recently, many of the best chemical and biological minds have turned toward peat and muck as a source of supply.

Availability of Peat.

Peat exists in tremendous quantities in all quarters of the globe. It is rich in nitrogen and carries an abundance of organic matter, the presence of which is so essential to soil fertility.

When the absolute necessity of organic ammoniates is considered, together with the enormous quantities of muck material now conserved in the form of peat and muck, it would seem that Providence had expressly decreed this state of affairs.

Let us not infer, however, that all that is necessary is to dig raw peat or muck, use the same as animal or blood tankage, and obtain as beneficial results. Far from it, and it is this field that now opens up new opportunities to the industrial and biological chemist.

To fully understand the situation and its possibilities, it is necessary to consider the method of formation of these peat and muck deposits, and to consider this in the light of the function of decaying organic matter or humus in soils.

The normal cycle of organic matter calls for the synthesis of compounds by plants through the energy derived from the sun. After death, the products so formed are decomposed largely through the activity of micro-organisms, eventually becoming the same compounds from which the complex organic body was first formed.

But for the existence of unfavorable environmental factors, this same fate of complete decomposition or mineralization would have befallen the vegetable matter now conserved as peat and muck. Anaerobic conditions produced by the large quantity of water and organic acid formed by the decomposition are probably the chief agencies which have prohibited complete mineralization.

The problem of economic and beneficial utilization of the organic nitrogen of peat and muck concerns itself primarily therefore with the rectifying of conditions so that the cycle of decomposition, interrupted for ages because of adverse conditions, may again be renewed.

Problems of Peat Utilization.

Obviously the first essential is to remove the excess water through drainage. Secondly the acidity must be corrected. Of even greater importance however is the fact that a proper microbial flora must be introduced. Through all the years that the peat has laid under the unfavorable conditions, the original flora has been replaced by inferior species of micro-organisms. The beneficial types of decomposition are accomplished by more or less well defined microbial species, and these must again be introduced to complete their interrupted labors.

In England, thanks to wide newspaper comment, Bottomly has been able to show the benefits and results obtained from peat treated according to his especial prescription. In essence, his method consists of introducing a decomposing flora after having first rectified the acidity. Upon the completion of this process, the material is sterilized and a new flora, consisting largely of the independent nitrogen gatherers (Azotobacter sp.), is introduced. Making use of the organic substance first produced, these organisms fix additional nitrogen from the air. The product has been tried in only a small experimental way, and even though the process is entirely revolutionized in the light of further research, it marks a step in the right direction.

In this country, Mr. Hoff, of the Alphano Humus Company, was probably the first to appreciate the possibility of the utilization of such organic nitrogen. His method of preparation is much more comprehensive and concerns itself with the physical state of the material as well as the chemical and bacteriological.

Cultivation of the Deposit

The first step is naturally that of drainage and proper clearing of the deposit. Crops of onions, lettuce and celery, to which such formations are admirably adapted, are grown for from four to ten years. During this time heavy applications of lime, potash and phosphorus are made in order to thoroughly rectify conditions for the best microbial development as well as the higher plants.

The benefit brought about through cultivation is such that the mass is finely disintegrated, and upon drying it is much like dried blood from the physical standpoint. As prepared commercially by Mr. Hoff, the surface layers are removed by means of electric scrapers after thorough sun drying. The material is removed to a big compost pile containing from twenty to thirty thousand tons.

Just enough bacterial life exists to cause a mild heating without fire fanging, and the introduction of the proper types of bacterial life as well as proper chemical substance to favor that life was one of the biggest problems that confronted the industry. At present, a very satisfactory method of treatment has been worked out, but it still demands much study even after ten years of investigation. One trained in both chemistry and bacteriology is required for any type of investigational work in this field.

Introduction of Nitrifying Bacteria.

After composting, the material is passed through hot air driers and only enough moisture left to favor the persistence of the microbial population remains. A new flora consisting largely of the nitrifying bacteria, the independent nitrogen gatherers, (Azotobacter) and the symbiotic nitrogen gatherers (Radicicola) are then added, together with other chemicals which render the material more conducive to their development.

These organisms probably constitute the best type of beneficial flora and are present in numbers ranging from two to five hundred million per gram.

To what extent chemical fertilizers can be combined with such material without destroying the beneficial flora is an important problem to be solved in connection with the utilization of prepared humus as an ingredient of mixed fertilizers.

If we are to draw any lesson from the study of the past fertilizer history, it would point to peat and muck as the coming source of organic ammoniates. The use of animal tankage was at first ridiculed as rank folly, but gradually it has become the most highly prized fertilizer ingredient. Garbage tankage experienced the same ridicule, only to come to a position but little less esteemed.

Peat and muck nitrogen has had even more serious prejudice to overcome, but with diligent research and with the aid of proper bacterial and chemical treatment, this material will become just as highly valued. It is the one last source of organic ammonia that exists in large enough quantity and is at the same time cheap enough to make its use as a fertilizing material possible.

Because of the fact that this problem of organic nitrogenous fertilizer has come to stay and will not be alleviated with the termination of the war, it would seem that it offers one of the richest fields for investigation by the industrial bacteriologist and chemist.

POSSIBILITY OF THE RECOVERY OF POTASH FROM BANANA STALKS

In a communication to the "Journal of Industrial and Engineering Chemistry," H. E. Billings and A. W. Christie recall attention to the discovery made last year by Ellis, through an ash analysis of the banana stalk, of the surprisingly high percentage of potash in this material. The possible treatment of such material for the recovery of its potassium suggested to Billings and Christie a line of experimental work, the results of which they give in the communication above referred to. The following extracts from their paper indicate the great possibilities opened up by their experiments:

"The stalks were chopped into pieces about one-inch long and dried in the oven. The dried samples were exceedingly friable and easily broken or ground in a mortar. A sample was analyzed for fertilizing constituents with the following results:

	Per cent.
Total nitrogen (N)	0.44
Total phosphoric acid (P_2O_5)	0.42
Total potash (K_2O)	10.46
Water-soluble potash (K_2O)	7.72
Moisture	4.05

"The dry matter is as rich in potash as commercial kainit and may be considered nearly as valuable, since 74 per cent. of the potash is soluble in water. Were this material used as a fertilizer it is reasonable to assume that the organic matter would in time decompose in the soil with the formation of humus, resulting in the subsequent release of the remainder of the potash in an available condition. This material also approximates the composition and value of dried kelp, which at the present time is being used to a considerable extent as a filler in commercial fertilizers. In certain respects, the material under consideration is probably superior to kelp for this purpose. Especially to be noted is the fact that banana stalks contain only very slight amounts of sodium and chlorine whereas kelp contains such quantities as to throw it into the class of kainit or other chlorinated salts.

Weighed amounts of the dry matter were charred sufficiently to destroy organic matter and the resulting char leached with successive small portions of distilled water. About 16 per cent. of the dry matter was recovered in the form of water-soluble salts. A maximum yield was obtained with water representing five times the weight of original dry matter. The salts were dried to constant weight at 100 degrees C., and analyzed with the following results:

	Per cent.
Silica (SiO_2)	2.81
Iron oxide (Fe_2O_3)	None
Alumina (Al_2O_3)	None
Manganese oxide (Mn_3O_4)	None
Lime (CaO)	0.12
Magnesia (MgO)	0.07
Potash (K_2O)	64.23
Soda (Na_2O)	0.46
Sulfuric Acid (SO_3)	4.17
Carbonic acid (CO_2)	26.11
Chlorine (Cl)	1.57
Phosphoric acid (P_2O_5)	0.34
Total per cent	99.88

The above figures show that the leached salts consist of over 90 per cent. potassium carbonate.

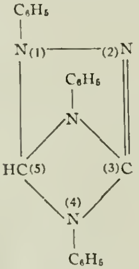
"NITRON"

As a Gravimetric Reagent for the Analysis of Substances Used in Explosives

By W. C. Cope and J. Barab*

The Object of This Paper Is to Collect the Rather Scattered Information Regarding "Nitron" and Its Applications, Add to It the Work Done in the Laboratory of the Pittsburgh Station of the Bureau of Mines, and Compile the Matter in a Comprehensive Form That Will Enable One Intelligently to Make a Hasty Survey of the Subject. This, It Is Hoped, Will Lead to Further Investigations and Result in the Use of "Nitron" for Many Analyses Which at Present Are Rather Involved.

"Nitron," discovered by Bausch[1] is the commercial name given to 1,4-diphenyl-3,5-endoanilodihydrotiriazol. Its formula is $C_{20}H_{16}N_4$ or



It is a basic substance forming salts with acids, a great number of which are practically insoluble in water. It is soluble in alcohol, benzene, chloroform, acetone, acetic acid, and acetic ether, slightly soluble in ether, and almost insoluble in water. Owing to its high molecular weight (312.2) it is particularly adapted as a gravimetric reagent for the compounds with which it forms practically insoluble salts. Busch[2] gives the solubilities of the following addition products, which "nitron" forms with acids: Bromide (1 in 800), iodide (1 in 20,000), nitrite (1 in 4,000), chromate (1 in 6,000), chlorate (1 in 4,000), perchlorate (1 in 50,000), nitrate (1 in 60,000). He[16] also states that "nitron" picrate is practically insoluble in water (1 in 250,000). Visser[13] claims that oxalic and salicylic acids also form insoluble precipitates. Sulphuric, hydrochloric, formic, acetic, boric, benzoic, tartaric, citric and phosphoric acids yield double salts. Visser has also applied "nitron" as a microscopic reagent for distinguishing many of its slightly soluble salts.

"Nitron," however, has found its most general application as a gravimetric reagent for nitric acid and its salts. Busch[8] recommends the use of "nitron" for the estimation of organic nitrates, and nitric esters. Utz[15] gives a method for the analysis of picric acid which is with slight modifications similar to that of Busch for nitrocellulose. Utz gives results for picric acid varying from 14.21% to 17.06% N as compared with the theoretical of 18.34% N. Because of the fact that his samples were not entirely water-free, definite conclusions cannot be drawn as to the accuracy of these determinations; for no standard is given with which to compare them. Since these were the only references that could be found regarding the application of "nitron" to nitric esters or nitro-compounds, these methods were investigated further to see how general their application could be made.

Effects of Other Substances.

Several investigators have experimented on the effects of other substances on this method of determination of nitrates. Paal and Ganghofer[23] found that dextrin, even if present to the extent of 2%, does not interfere with the complete precipitation of "nitron" nitrate, if enough time is allowed. Peptone interferes to some extent, but its influence may be overcome by adding a sufficiency of sulfuric acid. It may be removed from the solution by heating on the water bath for several hours, after adding formaldehyde, and the results of the "nitron" precipitation are then quite satisfactory. Gelatin if present to the extent of less than 0.5% does not interfere. It may be removed from the solution by the addition of tannin, the excess of which is then precipitated by means of normal lead acetate. A cold water extract of meat may be analyzed for nitrates after removing the interfering substances by the addition of normal lead acetate to the boiling solution; if alkaline, some acetic acid should be added. Hes[17] states that the presence of aluminum sulfate, magnesium sulfate, ammonium sulfate, potassium phosphate, magnesium chloride, tartaric acid, citric acid, sucrose and dextrose are without influence on the precipitation of "nitron" nitrate. When oxalic acid is present, the results obtained are too high. (Paal and Ganghofer, cited above, avoid the effect by the addition of H_2SO_4.) Chloric acid precipitates "nitron" quantitatively as "nitron" chlorate if the solution contains about 0.25% of chloric acid. Nitric acid and chloric acid may be determined together in the same solution if the amount of one of the acids is known. In this laboratory the effect of chloric acid is overcome by reduction with SO_2 or formaldehyde.[28] Adan[12], states that, if nitrites are present, the results obtained are high by an amount which does not correspond with the content of nitrite. Busch[7] analyzes a mixture of nitrites and nitrates, by first determining the nitrites by oxidation with permanganate and then precipitating the total nitrate in a separate portion as "nitron" nitrate after oxidation of the nitrite with hydrogen peroxide. Franzen and Löhman[18] comment on this method as follows:* "The usual volumetric methods for the estimation of a mixture of nitrous and nitric acids are inapplicable to bacteriological cultures; good results are obtained with "nitron." Busch's method is used, in which the total nitric acid is estimated after the nitrous acid has been oxidized to nitric acd by hydrogen peroxide, and the residual acid determined after the decomposition of the nitrous acid by hydrazine sulfate.

---

*From a contribution to the Journal of the American Chemical Society, Vol. XXXIX, No. 3, from the Explosives Chemical Laboratory, U. S. Bureau of Mines.

"The estimation in the presence of 'bouillon solution' gives too low results, owing to the retention of some 'nitron' nitrate in colloidal solution. If this is prevented by the addition of 2 to 2.5 cc. of concentrated H_2SO_4 per 200 cc. of solution, the estimation on the presence of 'bouillon solution' is as accurate as in water only. Since oxalic acid is a common constituent of bacteriological cultures, the presence of sulfuric acid has an additional advantage of preventing the precipitation of 'nitron' oxalate. A somewhat large excess of 'nitron' should be used."

Many modifications have been advocated for nitrate determinations by "nitron" by various investigators and indeed some have discarded this reagent because they were unable to get satisfactory results. "Nitron" has been used in this laboratory for several years, and some of the most accurate determinations of nitrates have been made with it. The method found most suitable for our work is very similar to the one proposed by Gutbier[3] and previously reported in one of this Bureau's publications.[26]

PREPARATION OF REAGENT.

To prepare the reagent one gram of "nitron" is dissolved in 10 cc. of 5% acetic acid (heating is unnecessary); the solution is filtered through an alundum crucible and placed in a dark bottle. The solution decomposes in the light and does not keep well, hence it is best to prepare it in small quantities as needed.

DETERMINATION OF NITRATES.

To the solution of nitrate, containing preferably not over 0.10 to 0.15 g. of nitrate, diluted to about 80 cc., add 12-15 drops of H_2SO_4 (2 acid to 3 water) heat to the boiling point, add 10-12 cc. of the "nitron" solution, stir, and let stand ½ to ¾ of an hour. Long, silky, needle-like crystals of "nitron" nitrate separate out on cooling. Place the breaker in ice water for 1½ hours and filter the crystals on a Munroe or Gooch crucible, using slight suction. Use part of the filtrate for washing out the beaker. Wash the precipitate with a total of 10 cc. of ice water, in 2 cc. portions and dry at 105° for one hour, which is usually sufficient to insure complete dryness. To confirm complete precipitation, heat the filtrate to boiling, add a little more of the reagent, and cool the mixture as before.

The molecular weight of "nitron" is 312.2, of "nitron" nitrate 375.2. Thus the nitrate being six times as heavy as HNO_3, an error in the weight of the precipitate is reduced to one-sixth when expressed as HNO_8, or to 1/27 when expressed as nitrogen.

SAPONIFICATION OF NITRIC ESTERS.

The nitric esters of importance used as explosives are the polynitrates of certain polyatomic alcohols. The polynitrates of glycerol, mannite, and in fact most of the common nitric esters have been branded with the misnomer of nitroglycerin, nitromannite, etc. Common practice sanctions the use of these misnomers and they are accordingly used in this paper.

When nitric esters are saponified they readily split off the nitrate groups. The alcohols, however, reduce the nitrate to nitrite* and probably under certain conditions are reduced as far as ammonia. To overcome the reducing action of the alcohols and at the same time to effect a complete conversion of all the nitrogen into nitric acid, it is necessary to use a strong oxidizing agent.

In the method worked out by Busch 3% hydrogen peroxide is used for this purpose. The procedure as given by Busch and used in this work may be briefly stated as follows:

About 0.2 g. of nitrocellulose is introduced into a 100 cc. Erlenmeyer flask, and 5 cc. of 30% aqueous caustic soda and 10 cc. of 3% hydrogen peroxide are added. The solution is heated on the water bath until frothing ceases, and then heated over a free flame to complete solution. 40 cc. of water and another 10 cc. of 3% hydrogen peroxide are then added and the liquid is heated to 50°. By means of a pipet 40 cc. of 5% sulfuric acid (sufficient to make the solution acid) are delivered at the bottom of the flask. The solution is heated just to boiling, and 12 cc. of the 10% "nitron" solution are added. From this point the process is exactly the same as for nitrates.

Results obtained in this laboratory by this method for nitric esters are given in the table on page 92.

As may be seen from the table, the determination by the nitron" method for nitrocellulose, nitromannite and nitrostarch, are quite satisfactory. The results for nitroglycerin, however, are not accurate enough for practical purposes. The figure 17.90% N was con-

---

*Taken from abstract, J. Chemical Soc. The English abstractors have made a curious error in referring to the "Bouillon Lösung" of the original as "Bouillon's Solution."

*Sidgwick in "Organic Chemistry of Nitrogen," page 9, makes the following statement in regard to nitroglycerin: "On (*b*) saponification (Robertson, *Chem. News*, 99, 289 (1909) the NO_3 groups are readily split off as nitric acid, but they oxidize the glycerol, and are themselves reduced to nitrous acid."

As there seemed some doubt as to whether metallic nitrates when once formed could be reduced to nitrous acid by the polyatomic alcohols, a simple direct experiment was made to determine this point. Three solutions were made up as follows:

1. Sodium nitrate, sodium hydroxide, glycerol, and water.
2. Sodium nitrate, sodium hydroxide, and water.
3. Sodium hydroxide, glycerol, and water.

Each solution was boiled for a few minutes, acidified with hydrochloric acid and tested with potassium-iodide starch test paper. The paper immersed in solution No. 1 was the only one which turned blue, the ones immersed in solutions Nos. 2 and 3 remained unchanged. The same experiment was tried with mannite in place of glycerol, with similar results.

This certainly leaves no doubt that certain alcohols will reduce sodium nitrate to sodium nitrite. From qualative tests it appears, however, that the alcohols will not reduce sodium nitrate after the metallic nitrate is once formed, to ammonia, but during saponification this probably occurs.

Determination of Nitrogen in Nitric Esters.

Substance	Per cent Nitrogen found by "nitron"	nitrometer
Nitrocellulose	13.13	13.15
	13.11	...
Nitromannite	18.24	18.33
	18.28	...
Nitrostarch	13.04	13.00
Nitroglycerin	17.90	18.40
	18.00	...

sistently obtained for many determinations of nitroglycerin. On investigating this matter further, it seemed evident that the glycerol resulting from saponification, exerted a much greater reducing action on sodium nitrate than most of the other alcohols liberated from nitric esters. For a number of determinations alcoholic caustic potash was tried, but owing to the further reducing effect of the added alcohol low results were again obtained. The method finally developed, which appeared to overcome these difficulties, was to use 30% aqueous caustic soda and 30% hydrogen peroxide. The method in detail follows:

Apparatus for Saponification.

The apparatus used for carrying out the saponification consisted of a 100 cc. Erlenmeyer flask with a ground glass air condenser 25 cm. long. A sample weighing 0.1000 g. is placed in the flask. A mixture of 5 cc. 30% NaHO and 5 cc. 30% H_2O_2 is added, and then about 15 drops of 30% H_2O_2 are introduced. The reflux condenser is attached and the apparatus placed in the water bath. After about 10 minutes, when the evolution of gas becomes very mild, 10-15 drops of 30% hydrogen peroxide are again added. This operation is repeated over a period of two hours, then twice at ½ hour intervals. By this time the small drop of nitroglycerin has disappeared from the surface, and further heating on the water bath will not accomplish any further saponification. About 8% of nitrogen is converted into nitric acid up to this point.

The reflux condenser is removed, 10-15 drops of 30% hydrogen peroxide added, a small Kjeldahl connecting bulb (to prevent splashing) is inserted into the Erlenmeyer by means of a rubber stopper, and the flask is heated for a few minutes over a free flame. The addition of H_2O_2 and heating is repeated twice and the solution is finally boiled down to a volume of about 3 cc. 40 cc. of water and 10 cc. of 3% H_2O_2 are added and the liquid is heated to 50°; the solution is acidified with 40 cc. of 5% sulfuric acid and the determination is completed in the same manner as for nitrocellulose. Results obtained for this method for nitroglycerin were 18.20, and 18.22% as compared with 18.40% obtained by the nitrometer.

Application to Nitrocompounds.

This method was then tried on several nitrocompounds, the results of which are given in the following table:

Substance	Per Cent N. Aqueous NaOH 30%	Alcoholic KOH 20%	Theoretical (total)
Tetranitromethylaniline	13.17	16.19	24.4
Tetranitroaniline	18.70	18.86	25.6
Trinitrotoluene	14.68	15.25	18.5

These results clearly show that the decomposition of nitrocompounds qualitatively into nitric acid cannot be readily obtained by this method.

The fact, however, that a large portion of the nitrogen of the nitro group is converted into the nitrate group indicates that it might be made quantitative by some variations of the method.

"Nitron" as an Aid in Differentiating Between Nitrates and Nitrocompounds.

In a recent article* we called attention to the fact that the nitrometer could not be used as a means of determining whether certain substances were nitrocompounds or organic nitrates. "Nitron" precipitates nitrates as "nitron" nitrate, while with nitrocompounds it either forms no precipitates, or one which is an addition compound of "nitron" with the nitrocompound, e.g., "nitrontrinitrocresolate." In the latter case the addition compound is readily distinguishable from the nitrate by the appearance of the precipitate. For specific examples urea nitrate, guanidine nitrate, nitrourea and nitroguanidine were investigated. Urea nitrate and guanidine nitrate both gave precipitates of "nitron" nitrate, but nitrourea and nitroguanidine gave no precipitate.

Urea nitrate gave 11.38 and 11.37 (theoretical 11.38%) N, and guanidine nitrate gave 11.16 and 11.21 (theoretical 11.46) N. The latter substance was not purified and the amounts found probably represent the true nitrogen content. "Nitron" therefore affords an additional means of differentiating between nitrates and nitrocompounds.

Determination of Picric Acid and Allied Substances.

As previously stated, picric acid forms a practically insoluble addition compound with "nitron." The following method was used for this determination:[16] 0.2000 g. of picric acid or its salt, is dissolved in 150 cc. water and 12-15 drops of 2:3 H_2SO_4 are added. The solution is heated to boiling and 10-12 cc. of 10% "nitron" solution are added. A bright yellow precipitate forms immediately, which is allowed to cool to room temperature for about two hours. It is unnecessary to cool these compounds in ice water. The precipitate is then filtered on a Munroe or Gooch crucible, dried for 1 hour at 105°, and weighed.

As trinitrocresol is very similar to picric acid in most of its reactions, a few determinations with "nitron" were made to ascertain whether this method is applicable to trinitrocresol and its salts.

---

*Jour. Am. Chem. Soc., 38, 2552 (1916).

PICRATE AND TRINITROCRESOLATE DETERMINATIONS.

Substance.	Wt. gram taken.	Cc. water required for solution.	Wt. subst. found.	Remarks.
Ammonium picrate........	0.2006	150	0.2007	C. P.
	0.2008	...	0.2008	
Trinitrocresol	0.1500	150	0.1502	Crystallized
	0.1500	...	0.1497	from alcohol
Ammonium trinitrocresolate.	0.1500	75	0.1465	
	0.1500	...	0.1470	Not purified

Phenol and the mono- and dinitrophenols were also tested in the above manner, but none gave a precipitate. 0.1000 g. 1,2,4-dinitrophenol dissolved in 200 cc. of water gave a copious yellow precipitate with "nitron" solution when no H_2SO_4 was added. This precipitate was filtered, washed, dried and weighed in the usual manner. Calculated on the basis of an addition product it gave 0.1009 g. dinitrophenol.

This immediately suggested a new method for the analysis of a mixture of picric acid and dinitrophenol. The following procedure was adopted:

0.1505 g. picric acid and 0.0500 g. dinitrophenol were dissolved in 250 cc. of water and heated to boiling without the addition of acid, and 12 cc. "nitron" solution were added. The mixture was cooled to room temperature for 2 hours, filtered, washed, dried at 105° for 1 hour, and weighed. This procedure was repeated on a similar sample, but with the exception that 15 drops 2:3 H_2SO_4 were added previous to boiling.

DETERMINATION OF A MIXTURE OF PICRIC ACID AND DINITROPHENOL.

	Weights taken.		Weights found.	
Conditions.	Picric acid.	Dinitrophenol.	Picric acid.	Dinitrophenol.
Acid added.....	0.1505	0.0500	0.1539	0.0000
No acid added...	0.1505	0.0500	0.1539	0.0466
	....	....	0.1505(*a*)	0.0495(*a*)

(*a*) Calculated.

The calculated results are given to show the almost complete insolubility of the mixed precipitates, and are obtained by deducting the theoretical weight of "nitron" picrate from the total precipitate.

Busch and Blume[15] give very good results for determining picric acid in this mixture when it is acidified with sulfuric acid. According to their results the calculated values in the table are what should be expected in these determinations. To our knowledge a more accurate method for this analysis is not known.

While this particular analysis may not be of very great importance, the method here suggested should prove a rather fertile field for investigation, especially as regards analyses of complicated mixtures.

Determination of Perchlorates.

A few determinations were carried out with commercial C. P. ammonium perchlorate by the same method as for nitrates. 0.12 g. of perchlorate was taken. Its purity by this method was found to be 99.67 and 99.58%, while by the fusion method, 99.53% purity was obtained. These results were previously recorded[26] and as far as known this was the first application recorded of "nitron" for the determination of perchlorates.

Determination of Oxide and Nitrogen.

C. G. Storm, former explosives chemist of the Bureau of Mines, in March, 1910, applied "nitron" to the analysis of a mixture of gas containing NO and NO_2. Later Burrell and Seibert[30] adopted his method for the determination of oxides of nitrogen in mine air. To our knowledge no other adaptation of the "nitron" method has been applied to gas analysis.

The method may be outlined as follows: By means of a separatory funnel, 10 cc. of a 5% solution of potassium hydroxide and 10 cc. of a 3% solution of hydrogen peroxide were poured into a 2-liter bottle; the hydrogen peroxide to oxidize the nitrous fumes to nitric acid, and the potassium hydroxide to form potassium nitrate. The bottles were shaken frequently to insure complete oxidation and absorption. The solution was then washed into a beaker, the wash being used sparingly so that the total volume of solution was not greater than 30-40 cc. The solution was then made slightly acid with 10% sulfuric acid, the solution heated to boiling and 10 cc. of "nitron" solution added. It was then cooled, filtered, and the precipitate was washed, dried and weighed in the usual manner. Theoretically 1 cc. of nitric oxide requires 0.01344 g. of "nitron," and 1 cc. of nitric oxide is equivalent to 0.0168 g. of "nitron" nitrate.

RESULTS OF GAS ANALYSIS WITH THE "NITRON" METHOD.

Sample No.	No. present, cc.	No. found, cc.	Sample No.	No. present, cc.	No. found, cc.
1..........	3.7	3.5	6..........	0.2	0.2
2..........	2.4	2.4	7..........	0.2	0.2
3..........	2.8	2.6	8..........	0.8	0.6
4..........	0.9	0.6	9..........	1.7	1.5
5..........	2.7	2.5			

Results obtained by Burrell and Seibert on measured amounts of nitric oxide, prepared in a Lunge nitrometer from pure nitrates, are given in the preceding table.

They comment on these results as follows:

> "It is shown from the above results that with a sufficiently large sample of mine air (5 or 10 liters) quantities of nitric oxide much below that required to produce harmful effects on men can be detected by this method."

When a mixture of NO and NO_2 are present the NO may be determined by absorption in $FeSO_4$ solution and the difference will be NO_2.

Recovery of Reagent.

"Nitron" varies in price from four to six dollars per ounce, and as its recovery is a simple matter, it is usually worth while to save the "nitron" precipitates and filtrates.

The filtrate and washings are made slightly alkaline with ammonia and the precipitated "nitron" filtered and washed with water. The "nitron" precipitates, along with the asbestos mats collected from the crucibles used in the determinations, are added to dilute ammonia solution and warmed to 60°. The precipitated "nitron" with asbestos is quickly filtered under slight suction and washed with cold water. The mass is then digested in 5% acetic acid until the "nitron" has dissolved, and again filtered. The filtrate is then made slightly alkaline with ammonia and the "nitron" filtered off. It is then washed with cold water and dried in a vacuum. Decomposition may be avoided by conducting the filtering and washing in an atmosphere of inert gas and as much as possible away from light.

Conclusions.

1. The methods employed and the results obtained

in this paper by the use of "nitron" clearly show its advantages in the following respects, over other general methods employed for the determination of nitrogen in substances containing it, such as the Dumas, Kjeldahl, and nitrometer methods:

(*a*) Manipulation is simpler.

(*b*) Less time is required.

(*c*) The necessary apparatus is simple and inexpensive.

(*d*) No special skill is required for following directions and obtaining good results.

2. Heretofore "nitron" was used directly as a precipitant in the analysis of nitric acid, perchloric acid, picric acid and their salts. Its use has been extended directly as a precipitant to the analysis of trinitrocresol and its salts, and to mixtures of picric acid and dinitrophenol.

3. "Nitron" has previously been employed to precipitate the nitrate formed on saponification of nitrocellulose. The value of this method has been confirmed in this paper, and the same method is extended for the analyses of the nitric esters of mannite and starch.

4. The failure of the saponification method as applied to nitrocellulose is shown in the case of nitroglycerin, and a modification of the method is developed which is applicable to nitroglycerin.

5. The addition compounds of "nitron" with picric acid and trinitrocresol are shown to be the most insoluble compounds which the trinitrophenols form.

6. The analysis of a mixture of dinitrophenol and picric acid by the use of nitron is the simplest method known for such mixtures.

7. By treating true nitro compounds with a solution of alkaline peroxide it is not possible to convert quantitatively the NO_2 group to the NO_3 group.

FACTORS FOR NITRON DETERMINATIONS.

ULTRA VIOLET LIGHT.

Its Application in Chemical Arts.

By Carleton Ellis and A. A. Wells.*

This Is the Third Installment of an Article Dealing with Investigations Conducted by the Writers Into the Possible Applications of Ultra Violet Light, and the Results Obtained Following the Exposure of Various Elements and Compounds to the Action of Its Rays. The Present Installment Continues a Discussion of the Work of Other Investigators. Part IV Will Appear in the Next Issue.

PART III

FURTHER NOTES ON HALOGEN COMPOUNDS AND HALOGENATION.

According to the process of *Tompkins* (British Patent 780, Jan. 18, 1915; J.S.C.I., 1915, 1225) coal-gas, rich in ethane, is produced by distilling coal at a low temperature e.g., 500-600° C. The *ethane*, together with a little *ethylene*, is separated by liquefaction, then again converted into gas, mixed with a suitable quantity of chlorine, and chlorinated by exposure to actinic light from a quartz lamp. The hydrogen chloride produced in the reaction is absorbed in water and used to prepare a solution of a chloride, e.g., zinc chloride, from oxide or carbonate, the solution being afterward electrolyzed to produce chlorine for use in a subsequent chlorination process. The coal-gas may also be chlorinated direct, in which case the actinic power of the light must be kept below that which would cause appreciable chlorination of the methane present.

Brooks, Essex and Smith (U. S. patent 1,191,916, July 18, 1916) describe a process of chlorinating liquid hydrocarbons, such as *gasoline*, and *petroleum oils, benzol, toluol, etc.*, in which a temperature-controlled body of such liquid hydrocarbon is treated with chlorine under the influence of actinic light. The chlorine is introduced at a point in the liquid body remote from that at which the rays of actinic light enter, as by illuminating a body of liquid hydrocarbon from the top while introducing chlorine gas at the bottom. For example, gasoline, or a fraction obtained by distilling gasoline, is placed in an opaque vessel having means for controllable illumination at one end, a mercury vapor lamp, or a nitrogen filled tungsten lamp, provided with a rheostat, being used. At the bottom of the container an inlet is provided for introducing gaseous chlorine. Means are also provided for agitating the liquid. As the light shines through the liquid it causes reaction of chlorine and the hydrocarbon. If the liquid is not circulated, the upwardly diffusing chlorine and the downwardly passing light soon establish a zone of maximum reaction somewhere between the top and the bottom. If the liquid be circulated, the action is somewhat different, since circulation will bring a greater or less amount of chlorine containing liquid under the influence of the light rays. In so doing the concentration of the dissolved chlorine in the liquid in the illuminated zone is always small, there always being a large excess of hydrocarbon over chlorine in the zone where action is taking place. This is stated to conduce to smoothness of reaction in forming monochlor derivatives. With artificial circulation the reaction is more uniform Chlorine, dissolving in the oil, colors it yellow and as the chlorine disappears from solution by reaction with the liquid, the color of the liquid is discharged. The active light rays pass through the uncolored oil, but not through the colored. Hence the less the amount of dissolved chlorine, the better the penetration of the light rays. The reaction chamber is provided with a heating and cooling coil and a reflux condenser is used when the operation is carried on with heating. Means are provided for removing and collecting the hydrochloric acid formed. In making mixed *butyl, pentyl, hexyl*, etc., *chlorides* for the manufacture of artificial "amyl acetate" the chamber is filled with a liquid gasoline fraction, distilling between 25° and 45°C., and chlorine is introduced into the liquid in minute bubbles. As these pass upward they are dissolved to a greater or less extent. The liquid becomes charged with chlorine from below upward, the most concentrated solution being at the lowest point. The chlorine solution is brought upwardly toward the light by agitation. The intensity of the actinic rays passing downwardly is diminished in proportion to the amount of chlorine in the solution and to the depth of the solution through which they pass. The amount of light therefore penetrating to the lower layers of gasoline containing greater amounts of chlorine is diminished to a degree permitting only a gentle action.

---

*All rights of publication in book form reserved by the authors, Consulting Chemists and Chemical Engineers, 92-98 Greenwood Ave., Montclair, N. J.

The maximum action of the light and of the chlorine takes place in a zone in which the gasoline is in large excess and the tendency of the action of the light is therefore merely to make the monochlor products; and not to induce further chlorination of mono compounds already produced. The chlorination is carried to a point where about 20 per cent. of the material is converted into mono-chlorides when the operation is interrupted and the unchanged oil is separated from the chlorides by fractional distillation. If dichlorides are to be produced, the process is the same, save that in lieu of charging the container with hydrocarbon, it is charged with mono-chlorides. If the material to be chlorinated is not a liquid, it may be melted or dissolved, as by using carbon tetrachloride. For example, paraffin may be melted and chlorinated by this process.

A process of *Brooks* and *Padgett* (U. S. patent 1,220,821, March 27, 1917) involves the production of non-volatile *unsaturated hydrocarbons* from *petroleum* oils, in which the use of ultra violet light is suggested. The product is stated to be suitable as a non-saponifiable substitute for linseed oil in paint compounds. For example, solar oil, is chlorinated in accordance with the reaction:

$$C_{15}\ H_{32} + 2Cl_2 \longrightarrow C_{15}\ H_{30}\ Cl_2 + 2HCl$$

thereby also obtaining hydrochloric acid as a by-product.

The dichloride thus obtained is then subjected to a high temperature, ranging from 350° C. to 550° C. in the presence of a catalyst when hydrochloric acid is split off with the formation of unsaturated hydrocarbon. The final product is found to have an iodine number varying from 120 to 150 according to the boiling point of the solar oil and is capable of absorbing oxygen with the formation of a "drying" film, such as is given by linseed oil.

Ellis (U. S. patent 1,202,040, Oct. 24, 1916) describes a process for the manufacture of *benzyl chloride* from toluol by the continuous circulation of toluol through an apparatus in which an excess of toluol vapor is produced and acted upon by chlorine at an elevated temperature to promote side chain chlorination, under gradually increasing temperature conditions and in the presence of actinic light to promote the chlorination. The benzyl chloride is then condensed and removed and the remaining vaporous material subsequently condensed and the hydrochloric acid substantially eliminated before the remaining toluol is returned to the still for retreatment. The chlorine may be preheated before coming into contact with the toluol vapor. The treating chamber may be heated by an air heater or heating jacket. The treating chamber is subjected to the influence of actinic light after the reaction has been largely completed, mercury lights being arranged around the treating chamber adjacent to its discharge end. Quartz glass is used to permit full actinic effect. Catalyzing material may be added to the toluol, phosphorus pentachloride being used to advantage. The preliminary portions of the chamber may also be filled with fragments of pumice, porcelain, etc., these materials considerably promoting the reaction. The treated vapors leaving the chamber contain benzyl chloride, hydrochloric acid gas, and unchanged toluol vapor. The toluol is converted to the extent of a quarter or a half during each passage. These mixed vapors are passed through a dephlegmator to collect the benzyl chloride. The remaining vapor passes from the dephlegmator into a condenser where the toluol is condensed and flows back into the still. The hydrochloric acid gas is eliminated by a separating chamber from which the gas is allowed to discharge. Additional toluol is continuously supplied to the system.

Ellis has also described (U. S. patent 1,146,142, July 13, 1915) a special form of chamber for chlorinating toluol through the agency of ultra violet light. Side chain chlorination is effected, producing *benzyl chloride, benzal chloride* and *benzotrichloride*.

According to *Ransford* (British patent 16,317, July 8, 1914; J.S.C.I. 1915, 1203) tetrachlorotoluene is obtained by passing dry chlorine into toluene in the presence of iron or anhydrous iron chloride at 12-15°C., the mixture being agitated. When trichlorotoluene crystallizes out, the mass is melted by heating to 45-50°, then cooled to 35°C., and chlorine again introduced, gradually increasing the temperature to 50°C., until the necessary increase in weight has occurred. Only traces of pentachlorotoluene should be shown by precipitation on dilution of a sample with an equal volume of carbon bisulphide. On fractional distillation a yield of 90% of the theoretical quantity of tetrachlorotoluene is obtained. Further chlorination at 100-130°C. in presence of light, particularly ultra violet rays, gives *tetrachlorbenzal chloride*.

In *brominating hydrocarbons* or effecting other reactions promoted by a mercury vapor light, *Keyes* (U. S. patent 1,198,356; Chem. Abs. 1916, 2815) proposes that one of the reacting substances, e.g., bromine, be fed from a flask, into a quartz vessel, provided with a mercury vapor lamp, made integral with the flash and having a stirrer, a condenser and inlets and outlets. In another form of apparatus for similar use a vacuum jacket is interposed between an annular reaction chamber and a mercury lamp, to prevent deleterious heating of the reacting substances by the lamp.

The action of light on *iodine* and on *starch iodide* in water has been studied by *Bordier* (Compt. rend. 163, 205-6, 1916; Chem. Abs. 1916, 2669). To one litre of water were added ten drops of 10% alcoholic solution of iodine, to the same volume containing a little fresh starch paste were added three drops of 10% iodine. Both suspensions were decolorized when exposed to light for a few hours, while similar suspensions not exposed retained their color. Yellow glass did not prevent or retard the action. Bordier suggests that the violet or ultra violet rays remove the charges from the colloidal particles of iodine and starch iodide, and the iodine then combines with the hydrogen ion from the water to form hydriodic acid. After decolorization both suspensions showed acid reaction.

The influence of light on the gaseous systems *hydroiodic acid, hydrobromic acid, hypochloric acid,* and their components has been investigated by *Cohen* and *Stuckardt* (Z. physik. Chem. 91; 722-44, 1916; Chem. Abs. 1917, 749) from both sides of the equilibrium, at room temperature. The experiments have been carried out in quartz glass, uviol glass, and Jena glass, which permitted the determinations of the photochemical equilibrium in three different spectral regions. The percentage decomposition of the acid when equilibrium is attained is given below:

	In quartz glass.	In uviol glass.	In Jena glass.
Acid.	220 u.	254 u.	300 m.
Hydriodic	92.2%	100%	100%
Hydrobromic	100%	about 20%	0%
Hydrochloric	0.42%	0%	0%

The absorption of the halogen acids and the halogens in the ultra violet has been studied, and it has been found that it depends upon the thickness of the absorbing layer. Various conclusions regarding the position of the photochemical equilibrium in the different spectral regions are drawn from a consideration of the course of the absorption curves with increasing thickness of the absorbing layer.

Olivier (Rec. Trav. Chem. Pays Bas, 1916, 36, 117-125; J.S.C.I. 1916, 1149) states that when *para chlorbenzene sulphochloride* in ethereal solution is exposed to direct sunlight or the rays of a "uviol" lamp, chlorine is liberated and oxidation takes place with the formation of the free sulphonic acid. When the experiment is carried out by passing dry oxygen through the ethereal solution of the sulphochloride while exposed to the rays of the lamp, the quantity of chlorine collected shows a deficit as compared with the equivalent of sulphonic acid formed, and aldehyde and hydrochloric acid are found in the aqueous liquid on treatment with water. It is probable, therefore, that some of the chlorine reacts with the ether to form chlorethyl ether, which is subsequently hydrolyzed to aldehyde. Under favorable conditions, the decomposition of the sulphochloride under the influence of light and oxygen may amount to over 40% in six hours, and the reaction is practically inhibited in the absence of light or oxygen. The presence or absence of moisture has no appreciable influence. The photo-chemical decomposition of the sulphochloride is considerable in ethereal solution but only slight in chloroform solution. In benzene and carbon tetrachloride, the reaction does not take place. It is suggested that the formation of a peroxide may play a part in the reaction. Other sulphochlorides of the benzene series behave in a similar manner but to a lesser degree.

DIFFERENT EFFECTS OF ULTRA VIOLET LIGHT ON ORGANIC COMPOUNDS.

In an article on the effect of light on organic compounds *Gerretsen* (Chem. Weekblad 13, 220-32, 1916) states that the action depends on wave length; ultra violet light tends toward decomposition, while longer wave lengths are more apt to cause polymerization and condensation. In general, light favors endothermic reactions. The decomposition of *carbon dioxide* into carbon monoxide and oxygen caused at ordinary temperatures by ultra violet light, is proof of the powerful dissociating action of light. This effect is important in the photochemical synthesis of carbohydrates. *Hydrocarbons* in ultra violet light generally polymerize; e.g., *acetylene* yields *benzene* and a resinous substance. *Alcohols, aldehydes* and *ketones* decompose into carbon monoxide, hydrogen and hydrocarbons. Ethers decompose like alcohols, but yield less hydrogen and more hydrocarbon. *Acids* yield carbon dioxide and a hydrocarbon, with some carbon monoxide and hydrogen, probably due to preliminary reduction to aldehyde. *Dibasic acids* readily lose carbon dioxide, leaving the monobasic acid. *Keto acids* react the same with ultra violet light as with heat. *Esters* yield carbon monoxide, carbon dioxide, hydrogen and a hydrocarbon. *Sugars* react very much as with ferments. *Bioses* yield monoses; *trioses* a monose and a biose, which then yields two monoses. *Monoses* break up into carbon monoxide, methane and hydrogen. Some relation is to be expected between the absorption spectrum of a substance and its photochemical activity. According to *Henri* and *Wurmser*, the latter depends solely on that part of the absorption spectrum coinciding with the atomic groups affected by photochemical action. The rest of the light energy absorbed appears as heat. This gives the possibility that photochemical decomposition may differ with different wave lengths, depending on the groups responsible for absorption. Thus Bielecki and Henri were able to break up the absorption curves of *aldehydes* and *ketones* into simple elementary curves. Aldehydes gave two and ketones three curves. They conclude that rays of different wave lengths are absorbed by different groups.

Photochemical oxidations and reductions are either equilibriums affected by light, or complete decompositions. The temperature coefficient is always low. The solvent has some influence; thus, chloroform, benzene, carbon tetrachloride, or ethyl acetate solution is oxidized by ultra violet light to chlorine, carbon monoxide and water, but not in carbon disulphide, ethyl ether, ethyl alcohol or acetone solution. Many substances such as mercury chloride, iron chloride, iron nitrate, uranyl salts, oxides of iron, manganese and cobalt, etc., act as catalyzers of photochemical oxidations. The reaction $CH_3OH + KNO_2 = HC(OH):NOK + H_2O$ proceeds only in the light. Formaldehyde can be used instead of methyl alcohol. Further action of light gives substances containing a pyrrole or pyrrolidine ring, possibly identical with nicotine. This may give an insight into the synthesis of nitrogen compounds by plants. Intramolecular photochemical oxidations and reductions are quite common.

Photochemical polymerization, condensation and isomerization occurs in many cases. *Sugars* can be formed from formaldehyde in ultra violet light; but this hardly explains the presence of carbohydrates in plants, since sun light has very little effective ultra violet light. *Ketones* and *aldehydes* are especially susceptible to photochemical condensation. Many photochemical isomerizations are equilibriums which can be changed by changing the wave length. Those which reverse in the dark, Marckwald calls photoropic. In general, rays of high wave length change the labile to the stable form; ultra violet rays have the opposite effect. Photochemical hydrolysis is also very common; thus, most *esters* are saponified by water under the influence of light. The field of organic photochemistry, aside from its general significance, is very important in the study of structure.

EFFECT OF MOISTURE ON THE DECOMPOSITION OF CARBON DIOXIDE.

The action of ultra violet light on *carbon dioxide* has been determined at various pressures by *Coehn* and *Sieper* (Z. physik. Chem. 347-81, 1916; J. Chem. Soc. 110, 281-2; Chem. Abs. 1916, 2549). It is shown that an unchangeable stationary condition is set up with the time on exposing carbon dioxide to ultra violet light. The wave-length of the active light lies below 254. The decomposition is modified with increasing pressure more than is demanded by the law of mass action, as is also the case in the photochemical decomposition of water vapor. The decomposition is inversely proportional to the pressure. The photochemical decomposition of carbon dioxide is very sensitive to traces of water vapor, but in the opposite sense to all other photochemical reactions. For example, in the case where a dry gas is decomposed to the extent of 18%, the merest trace of moisture reduced the amount of decomposition to 0.1%. It is shown that neither formic acid nor formaldehyde is formed, and that the water undergoes no change. On the other hand it is shown that on illuminating a mixture of equal volumes of carbon dioxide and hydrogen with ultra violet light, *formaldehyde* is produced.

It is also found that *ozone* is stable in ultra violet light at 240°. Coehn and Sieper are unable to reproduce the results of Chapman in which it is shown that the presence of carbon monoxide increases the amount of ozone produced when oxygen is submitted to ultra violet light. Carbon dioxide is also shown by them to have no effect on the amount of ozone produced.

In the photochemical decomposition of *hydrogen peroxide* in dilute aqueous solution, Tian (J. Chem. Soc., 1915, 108, ii., 828-830; J.S.C.I., 1916, 114; Chem. Abs. 1916, 1960) finds the velocity increases with the increasing frequency of the exciting radiation, and when thin layers of solutions of varying concentration are exposed to the light emitted by a quartz-mercury arc lamp, the velocity is proportional to the intensity of the incident radiation and not to the absorbed luminous energy. This result is attributed to the heterogeneity of the radiation and the fact that rays of different wave-length are not absorbed in a constant ratio. The temperature-coefficient for the interval 10°-30°C. is 1.15. The velocity is slightly diminished by the addition of small quantities of acids and very considerably increased in the presence of traces of alkali. The reaction between hydrogen peroxide and ozone is accelerated by the action of ultra violet radiation. Whereas ultra violet rays of moderately short wave length (2500-3000) are able to bring about the decomposition of hydrogen peroxide at a measurable rate, pure water is only decomposed by rays in the extreme ultra violet. If the water contains dissolved oxygen, this reacts with the hydrogen set free in the primary photochemical decomposition of the water, and thus indirectly increases the rate of formation of hydrogen peroxide in that the velocity of the reversed reaction $H_2O_2 + 2H = 2H_2O$ is thereby diminished. At the same time, the dissolved *oxygen* is to some extent transformed into *ozone* under the influence of the ultra violet rays, and the ozone formed reacts with the hydrogen peroxide. Special experiments have shown that ozone has no action on water under these conditions. Conditions favorable to the formation of hydrogen peroxide are obtained (1) by the use of a source of ultra violet light which is rich in rays of very short wave-length; (2) by exposing the water to the action of the light in thin layers; (3) by eliminating as far as possible the factors which tend to bring about the decomposition of the hydrogen peroxide. This decomposition may be diminished by the use of pure water and of ultra violet radiation from which the rays of moderate wave-length have been cut off. The disturbing influence of ozone may be eliminated to a large extent by passing a current of air through the solution. The radiation from high-tension quartz mercury lamps which have been in use for some time is not nearly so rich in short-wave rays as the light which is emitted by new lamps of this type or that which is obtained from low-tension lamps.

The rays of the quartz mercury lamp according to *Gibbs* (J. Am. Chem. Soc 1912, 1193) color pure *phenol*, in the presence of oxygen, with remarkable rapidity. Samples exposed in small dishes covered with quartz plates are colored light red after an exposure of one minute.

UNION OF ACETYLENE AND METHANE.

According to a process described by *Heinemann* (U. S. Patents, 1,202,385, Oct. 24, 1916, and 1,134,667, April 6, 1915) the union of *acetylene* and *methane* is effected by heating these gases in the presence of catalytic metals, such as iron, nickel, copper, silver, platinum, iridium and palladium. Instead of using heat, the union of the acetylene and methane in the presence of catalytic metals is effected through the agency of ultra violet or other chemically active rays. For example, pumice stone, provided with a coating of copper, is dipped in a solution of chloride of platinum, and is dried. The salt is then reduced. In this way there is obtained a contact body consisting of two metals which are stated to exert a mutual balancing effect on one another, the more active property of the platinum group metal being mitigated by the less active property of the other metal associated therewith, and allowing the desired reaction to take place at a moderate temperature. A mixture of equal volumes of acetylene and methane is passed into a reaction tube containing the catalyst. During the passage of the mixture through the tube the reaction space is subjected to the influence of chemically active rays. When ultra violet rays are used a number of mercury lamps are supported in close proximity to the reaction tube.

BEER YEAST.

According to *de Fazi* (Ann. chim. applicata 4, 301-29, 1915; Chem. Abs. 1916, 950) the action of ultra violet rays is favorable to *alcoholic fermentation* for a relatively long time, (12 hours). *Beer yeast,* exposed to ultra violet rays for a definite time, increases in activity, and is not killed by the rays even after 14 hours' exposure. It is possible to select beer yeast by the action of ultra violet rays. The experiments were carried out in quartz flasks placed about 20 centimeters from a mercury lamp used as the source of the rays. A resume is given of previous work done on this subject.

EPINEPHRINE.

Epinephrine solutions were subjected by *Savapol* (Compt. rend. soc. biol. 77, 458-9, 1914; Chem. Abs. 1917, 489) to the action of ultra violet rays (by a method described by Parisot, Poeper and Crouzon) in order to determine if the action of epinephrine on erythrocytes is thereby modified. 1 c.c. of a 5:100 emulsion of sheep erythrocytes in 9:1000 sodium chloride solution was introduced into each of a series of test tubes all of which contained 1 c.c. of varying dilutions of epinephrine solutions which had been irradiated for periods of 10 min., 1½ hrs. and 3 hrs. The mixtures were kept at 37° for periods of 10-30 min.; control tubes contained non-irradiated epinephrine solutions. Agglutinations of erythrocytes without hemolysis was observed in tubes which contained epinephrine in the dilution of 1:5000. Hemolysis was produced with increasing intensity of greater concentrations (1:4000, 1:3000, 1:2000; 1:1000); the non-hemolyzed erythrocytes remained strongly agglutinated. Irradiation by ultra violet rays did not cause diminution of the hemolytic and agglutinating properties of epinephrine; on the contrary the agglutinating action was intensified to a certain extent, being produced more rapidly and completely. Corpuscle permeability was the same in the case of both normal and irradiated epinephrine.

According to Savopol (Compt. rend. soc. biol. 77, 460-1, 1914; Chem. Abs. 1917, 490), *Maric* has shown that a mixture of *epinephrine* and *tetanus toxin* can be rendered non-toxic by heating at 37 for 20 hrs.; Savopol has attempted to ascertain whether this neutralizing property of epinephrine on tetanus toxin is modified by irradiation of epinephrine by ultra violet rays. The technic previously adopted was employed. The periods of irradiation were 10 min., 1½ hrs. and 3 hrs. After determining the minimum lethal dose of tetanus toxin, (which was 0.001 c.c.) each of a series of white mice was injected with 1 c.c. of a mixture of epinephrine and tetanus toxin which had been kept at 37 for 20 hrs. Epinephrine lost its neutralizing action on tetanus toxin after a sufficiently prolonged period (3 hrs.) of exposure to ultra violet rays. An exposure of 10 minutes was sufficient appreciably to weaken this property without completely destroying it.

Savopol (Compt. rend. soc. biol. 77, 459-60, 1914; Chem. Abs. 1917, 89) states that *epinephrine hydrochloride* subcutaneously injected in 1:1000 solution in guinea pigs, causes local necrosis, and he attempted to determine whether epinephrine subjected to irradiation by ultra violet rays preserves this necrotizing property. A 1:1000 solution of Takamine epinephrine was placed in vacuo in a quartz vessel which was rotated rapidly (in order to prevent overheating and to equalize irradiation), the periods of exposure (to a mercury quartz lamp) being 10 min., 1½ hrs. and 3 hrs. The epinephrine thus irradiated was at once subcutaneously injected in guinea pigs. Necrotizing power was not modified by 10 minutes irradiation. This property disappeared completely, however, after 1½ hrs. irradiation, no more than a local inflammatory reaction being produced at the spot of subcutaneous inoculation.

MERCURIC CHLORIDE.

The action of ultra violet rays on *mercuric chloride* solution and on some *mercury salts* has been studied by *Pougnet* (Compt. rend. 161, 348-51, 1915; Chem. Abs. 1916, 863). A solution containing one gram mercuric chloride in 20 cubic centimeters of water, enclosed in quartz, was exposed at 15 centimeters to a mercury arc lamp. Mercuric chloride formed at once. The unreduced mercuric chloride found after 10 minutes was 0.831 grams; after 20 minutes 0.676 grams; 30 minutes 0.582 grams; 50 minutes 0.552 grams; 70 minutes 0.528 grams; 90 minutes 0.524 grams. Mercuric chloride suspended in water is slowly changed to mercurous chloride and mercury, the reaction becoming more rapid with time. Qualitative observations are appended on a number of salts of mercury dry and moist, under the rays. Most are darkened more or less; a few are unaltered.

PHOTOELECTRIC SENSIBILITY.

A Dolezalek electrometer was used by *Krüger* and *Taege* (Z. Elektrochem. 562-9, 1916; Chem. Abs. 1916, 720) to measure the photoelectric sensibility of *platinum* plates to light from a quartz mercury lamp, a special apparatus being used. The photoelectric sensibility was decreased by typical catalyzer poisons such as carbon monoxide, hydrocyanic acid and hydrogen sulphide, especially the last. After poisoning with hydrogen sulphide, the photoelectric sensibility was not wholly restored after repeated admission of air and evacuation again. Perhaps a film of platinum sulphide was formed, as has been assumed in other cases of poison. In the other cases the photoelectric sensibility was rapidly restored and there was a kind of exaltation, as is usual in such cases, and which is in agreement with the smallness of the effect in high vacuum. A part of the effect may be due to penetration of the gases into the metal film which makes it difficult to get reproducible results. Bombardment of the platinum with nitrogen was without effect, showing the electrochemical indifference of this element. Bombardment with carbon dioxide caused a small increase in the photoelectric sensibility; ammonia caused no increase. It appears that the easy emission of electrons (which corresponds to a high photoelectric sensibility) is closely connected with some catalytic process which cannot be explained without further knowledge of the catalytic process itself.

(To be continued in the June issue.)

ACCURATE SILICA DETERMINATION IN COMMERCIAL ANALYSIS

By

F. G. Hawley*

This Paper Is a Discussion of Methods of Silica Analysis, with Notes on the Errors Introduced by a Variation on the Amount, Strength and Temperature of Acid Used in Preliminary Reduction, and Length of Time Under Treatment. The High Cost of Platinum Has Led to the Introduction of a Method Employing Nickel Crucibles, Which Is Here Described In Detail.

Theoretically, the determination of "true" silica is a simple process, but it is found in commercial analysis that it is frequently a difficult matter to get satisfactory results. With careful work a chemist can usually get duplicate determinations to check within 0.3 to 0.4%, but frequently different chemists will not agree to within 2%. In view of these facts it would seem that chemists should investigate the cause of the errors and adopt some procedure that would at least tend to minimize these divergencies.

In "Bulletin 422" of the United States Geological Survey—"The Analysis of Silicate and Carbonate Rocks"—Dr. Hillebrand describes how an accurate SiO_2 determination can be made, but the method given is not suitable to commercial work where speed is necessary. Dr. Hillebrand and others proved long ago that there were three main sources of error in the method commonly used: A plus error from the small amount of SiO_2 from the flux; another plus error due to impurities retained by the SiO_2; and a minus error due to the solubility of the SiO_2 in the HCl.

In my experience the amount of SiO_2 introduced with the flux usually amounts to less than 1 mg. and a satisfactory correction may be easily made if the flux is measured. The amount of impurity retained by the SiO_2 may vary according to the elements present and to differences in the acid treatment, but generally amounts to between 0.1 and 0.3%. By far the largest and most troublesome error is the one due to the solubility of the SiO_2 in the HCl. This error is much greater than most chemists realize. I have known of several who carefully deducted 0.3 to 0.4% for SiO_2 from the flux and impurities in the SiO_2, but failed to add anything for the SiO_2 lost in solution, which in these instances was about 1.7%.

Dissolving of SiO_2 in HCl.

According to my observations the amount of freshly precipitated SiO_2 that dissolves in HCl, depends on the following conditions: First, the amount of acid present; second, the strength of the acid; third, the temperature; and fourth, the length of time the silica is in contact with the acid. There may be other conditions governing the solubility of SiO_2 in HCl, but these seem to be the principal ones. By far the most important is the amount of acid used.

Most chemists use acid of about the same strength to treat the dehydrated silica, and the assays are brought to a boil, insuring the same temperature, and are boiled for a fairly uniform length of time. Few, however, consider the importance of using a definite amount of acid. It seems to be a prevalent idea that the amount of silica dissolved by the acid solution is proportional to the amount of SiO_2 in the sample. When a small bulk of acid is used, this is certainly not the case. The experiments shown in Table 1 prove clearly that when a small amount of SiO_2 is present, the amount dissolved is proportional to the quantity of acid solution present and not to the amount of SiO_2 in the sample. These experiments were made on the standard sample of argillaceous limestone issued by the Bureau of Standards, which contains, according to the analysis made by Dr. Hillebrand and Dr. Waters, 18.15% of SiO_2.

---

*Chief Chemist, International Smelting Co., P. O. Box 351, Miami, Ariz. From Engineering and Mining Journal.

One-half gram samples were fused in platinum dishes with sodium carbonate dehydrated at 140° C., and run in the ordinary way except that varying amounts of 60% HCl were used. All were boiled five minutes, filtered, and the filtrate evaporated a second time to recover the SiO_2 dissolved.

Solubility of SiO_2 in HCl with Varying Amounts of Acids.

TABLE I.

No.	HCl Used, C.C.	SiO_2 on Filter, %	SiO_2 from Filtrate, %	Impurity in SiO_2 %
1	10	17.90	0.28	0.12
2	20	17.78	0.48	0.10
3	30	17.58	0.60	0.10
4	50	17.02	1.16	0.12
5	70	16.52	1.60	0.08
6	100	16.12	2.04	0.08

This experiment has been repeated many times by different chemists and always with similar results. Some text-books recommend using 50 to 100 c.c. of dilute HCl to dissolve the bases, but do not intimate that as much as 2% of SiO_2 may be dissolved from a sample that contains less than 20%, as shown in Table I.

Much light is thrown on this subject by the following experiment, in which different weights of an ore containing 70.8% SiO_2 were assayed in the usual way. The samples were all boiled two minutes with 10 c.c. of 60% HCl. The other conditions were the same except for the varying amounts of ore.

Solubility of SiO_2 in HCl with Varying Amounts of Ore

TABLE II.

No.	Sample Weight, Gram	Calculated SiO_2 in Sample, Gram	SiO_2 on Filter, Gram	SiO_2 from Filtrate, Gram
1	0.5	0.3540	0.3528	0.0014
2	0.5	0.3540	0.3516	0.0016
3	0.2	0.1416	0.1405	0.0015
4	0.1	0.0708	0.0696	0.0015
5	0.05	0.0354	0.0342	0.0013
6	0.02	0.0142	0.0136	0.0010
7	0.01	0.0071	0.0070	0.0008

This experiment has also been repeated several times with similar results and proves that the amount of SiO_2 that goes into the filtrate is almost constant and in no way proportional to the amount contained in the sample. This does not hold entirely true with samples containing less than 30 to 40 mg. of SiO_2 or when excessive amounts of acid are used.

The fact that nearly the same amount of SiO_2 is lost in the filtrate from a sample containing 10% as from one containing 70% naturally leads one to inquire why it does not all dissolve when present in very small amounts, or how SiO_2 that has once gone into the filtrate can be recovered by a second evaporation. The following seems to be at least a partial explanation: When the solution containing silica is evaporated, it precipitates as small flakes. As soon as the hot acid is added, these begin to dissolve very slowly. In samples containing 10% SiO_2 or more, the relatively large number of flakes, presenting a correspondingly large surface to the action of the acid, will quickly saturate it; consequently no more can dissolve from a high-grade sample, than from one containing about 15%. On the other hand, when the sample contains but little silica, there will be but few flakes and the rate of solubility of these will not be sufficiently rapid to saturate hte solution in the ordinary time taken for a determination. From this it must follow that when very small amounts of SiO_2 are to be determined, the acid solution should not be boiled longer than necessary.

To prove that the length of boiling has an influence on the results the experiments referred to in Table III were made, 0.5 gram of ore containing 24.1% of SiO_2 being used in each case.

Effect of Variation in Time of Boiling

TABLE III.

No.	25% HCl C.C.	Boiled, Min.	SiO_2 on Filter, Gram	SiO_2 from Filtrate, Gram
1	70	1	0.1146	0.0050
2	70	2	0.1138	0.0054
3	70	4	0.1130	0.0068
4	70	10	0.1120	0.0090
5	70	20	0.1117	0.0092
6	15	1	0.1182	0.0020
7	15	2	0.1186	0.0020
8	15	5	0.1188	0.0018
9	15	12	0.1194	0.0016

These experiments demonstrated that when there is considerable volume of acid solution, some time is needed to saturate it, and consequently the length of boiling time is of considerable importance. On the other hand, with only a small amount of acid solution it very quickly becomes saturated and so the length of time it is boiled is of less consequence. If boiled long enough, the solution may concentrate to such an extent that the dissolved SiO_2 will begin to reprecipitate. This is indicated in the last two experiments shown in Table III.

Table IV gives the results of experiments made to see what effect a variation in the strength of HCl would have on solubility. The results were rather surprising, as it was found that HCl of 15 to 25% strength would dissolve much more SiO_2 than stronger acid.

In each experiment 75 c.c. of acid was used and boiling was continued for five minutes.

Effect of Variation in Strength of HCl

TABLE IV.

No.	HCl %	SiO_2 on Filter, Gram	SiO_2 from Filtrate, Gram
1	80	0.1199	0.0030
2	40	0.1142	0.0064
3	25	0.1110	0.0095
4	15	0.1112	0.0095
5	8	0.1140	0.0060
6	4	0.1160	0.0054
7	1	.....	0.0038
8	0.5	.....	0.0022

The SiO_2 from experiments 7 and 8 was too badly contaminated with iron to weigh. From other experiments it was found that pure water has a very slight solvent action on SiO_2, which is greatly increased by the presence of NaCl. Considerable NaCl is always present from the action of HCl on the flux, and part of the solubility is undoubtedly due to this cause.

In a further series of tests (Table V) hot acid proved to be more effective in dissolving SiO_2 than cold. Stirring also affected the result. In these experiment 70 c.c. of 40% HCl was in contact with the SiO_2 for 10 min.

Samples 3 and 4 were placed in a water bath containing boiling water and heated as hot as possible.

From the results of this and the previous series of experiments it can readily be seen that adding boiling water to dilute the assay or washing the sides of the casserole should be avoided, as it would be equivalent to using a large volume of hot dilute acid, which would result in an excessive loss. Tests made to determine the most satisfactory temperature and length of time for dehydrating the SiO_2 indicate that heating to 120° to 150° C. for 30 min. gives satisfactory results. If heated to a higher temperature or for a much longer time, the solubility is slightly decreased but the silica will be contaminated by more impurities. Ordinarily, I find that boiling for three minutes with 15 c.c. of 60% HCl will give about as pure silica as could be obtained by boiling longer or with more or stronger acid.

EFFECT OF TEMPERATURE OF SOLUTION

TABLE V.

	Temperature	SiO_2 on Filter, Gram	SiO_2 from Filtrate, Gram
1..........	Boiled	0.1148	0.0068
2..........	Boiled	0.1146	0.0066
3..........	88°C stirred	0.1164	0.0048
4..........	88°C not stirred	0.1176	0.0040
5..........	70°C stirred	0.1176	0.0038
6..........	70°C not stirred	0.1186	0.0028
7..........	45°C stirred	0.1186	0.0022
8..........	45°C not stirred	0.1194	0.0020

A source of error not generally known is caused by the silica adhering to the casserole so tenaciously that it is not removed by ordinary rubbing. When the acidified solution is evaporated quite slowly to dryness, the silica has little tendency to stick to the casserole; but if the solution is evaporated rapidly, and especially if it is boiled, considerable silica sticks to the casserole and can only be partly rubbed off. The silica adheres mostly to the side at or near the surface of the liquid and forms a roughened ring. When first used, very little silica adheres to the casserole, but with each repeated usage the ring becomes larger and rougher and accumulates more. To reduce this error to a minimum the casserole should be kept as smooth as possible. To remedy the roughening, which is frequently mistaken for etching of the glaze, watch the casserole and as soon as a slight roughening is noticed, remove it carefully with dilute hydrofluoric acid. Place a spoonful of water in the casserole and then an equal amount of HF and quickly rub with a rubber finger cap or "policeman." As soon as no rough places can be felt, quickly empty out the acid and rinse well If these operations are carefully done, the glaze is not injured noticeably.

When making SiO_2 determinations on sulphide ores or ores containing much Cu, Pb, Sb or other easily reduced metal that would attack the platinum crucible, it is customary to give the sample a preliminary acid treatment to remove the objectionable metal and then determine SiO_2 on the insoluble residue. The necessity of this acid treatment, together with the high cost of platinum, led to the introduction a few years ago of a new method, using nickel crucibles and a flux of $Na_2O_2 + NaOH$, and eliminating the acid treatment.

This method is used extensively at a number of the large copper camps of the West. Several years ago I made an extensive series of tests to see how its accuracy would compare with the standard sodium-carbonate method. Many experiments were made on analyzed samples issued by the Bureau of Standards, and many comparative assays were also run by the two methods on regular work. These tests, which were carefully made, proved that with careful manipulation the new method is capable of giving as good results as the longer sodium-carbonate method. Most of the foregoing experiments were run by both methods.

The sodium hydroxide used in the new method reacts with the silica of the ore, forming sodium silicate and water. This water is in the form of steam, and if the fusion is started too hot the escaping steam may cause a slight mechanical loss. This will not happen if care is taken to start the fusion at a very low temperature and to increase the heat slowly.

In either method, after dissolving the melt and acidifying, the flux is changed to NaCl, and as the operations are the same from this point onwards and as the same salts are present in about the same quantity, there can be no difference due to the method.

My own modification of the peroxide method, as used for routine work, is as follows: Weigh 0.5 gram of pulp into a 30 c.c. nickel crucible and add one scoopful (about 4 grams) of flux composed of equal parts of sodium peroxide and sodium hydroxide. Mix the pulp and flux, and if the sample is known to contain over 50% of SiO_2 put on a cover to prevent loss. Fuse at a low temperature beginning much below redness and increasing very slowly until a dull red is reached. A good way to make the fusion is to set the crucibles in an iron tray having holes punched to accommodate them and constructed so that they are held about half an inch above the floor of the muffle. Introduce the tray with crucibles into the muffle at a low red temperature and fuse for three or four minutes.

The Life of Nickel Crucibles.

When the fusions are made as described the nickel crucibles can be used from 20 to 40 times, but if the temperature is too high, or if there is too much sodium peroxide in the flux, they will burn out much quicker.

Remove the crucibles and partly cool; place in 4-in. casseroles, and cover the crucibles with 2-in. watch glasses so placed that a slight opening is left on one side. Through this opening squirt in 2 or 3 c.c. of warm distilled water from a wash bottle. This should start a vigorous reaction between the water and the flux. As soon as the action has somewhat diminished add 3 or 4 c.c. more water and continue to do this until the fused mass is disintegrated. Toward the end the water should be added with enough force to thoroughly stir the contents. If the crucible gets too cold or the water is not hot enough, the action may cease before the melt is loosened from the crucible; and if too hot the contents may boil over. With a little practice the right conditions are readily found. As soon as the action ceases and the crucible is a little over half full, rinse off the watch glass and from a large burette add about 10 c.c. of 60% HCl in small portions so as to avoid too violent reaction; then add 90% HCl until it is in excess. The crucible should now be about full and everything in solution except possibly a little gelatinous silica.

With the fingers or platinum-tipped tongs, remove the crucible, rinse, and place the casserole on the hot plate to evaporate. No harm is done if it boils gently at first. When about half evaporated, place the casserole on an iron or aluminum ring so made that the bottom of the casserole is kept about one-quarter inch above the hot plate. These rings are very beneficial in preventing spitting. When the residue has become dry, cover with a watch glass and bake at about 135° C. for 30 min.; remove and when cool add 15 c.c. of 60% HCl and turn about so as to moisten all parts of the residue. Allow to stand a short time and then put on the hot plate, and with cover still on, boil for 3 min. Remove and allow to cool, rinse the sides down with the minimum amount of warm distilled water, and swirl around to loosen any crust still adhering to the sides. The NaCl does not all dissolve, but will readily do so in the wash water.

It is very necessary that the casserole should not be heated after rinsing down the sides with water. After standing a few minutes, transfer the contents to a filter and wash twice with warm water; then once with hot dilute HCl and add a little to the casserole. Rub the sides and bottom of the casserole to loosen any adhering SiO_2 and rinse into the filter. This SiO_2 is ground rather fine by the rubbing and has a tendency to clog the filter, hence it is better to add this after the main portion has been partly washed. Wash the filter twice again with water, place in a crucible, partly dry, and ignite strongly for ten minutes. Weigh the SiO_2 as soon as cool, for it is hygroscopic. A correction is now made for the SiO_2 lost in solution, which under these conditions will amount to about 0.4%. A deduction is made for impurities in the SiO_2 and the SiO_2 from the flux. These gains about balance the solubility loss. Occasional tests should be made to check losses and gains.

It is evident from the nature of the flux that some special method for preparing and storing it will be necessary. The following has proved satisfactory: Take a half-pound or more of pure dry NaOH and grind up, a few sticks at a time, in an iron mortar so that the largest pieces are no larger than a grain of wheat. The grinding must be done quickly, or the NaOH will absorb moisture. Place it in a wide-mouthed jar and add an equal amount of Na_2O_2 and mix by rotating. A satisfactory jar to use is a small 4-in. straight-sided desiccator with a circular piece of gasket rubber for a cover. The jar should be opened as seldom as possible, but in spite of this precaution the flux will slowly absorb moisture. This moisture reacts with the sodium peroxide, changing it to hydroxide, probably according to the following equation:

$$Na_2O_2 + H_2O = 2NaOH + O$$

From this it will be seen that the H_2O is chemically held and so the flux will still be dry, but the oxidizing power is lost. When such flux is used, the fusions will fail to disintegrate properly when hot water is added. The remedy is to add more Na_2O_2 from time to time.

DEVELOPMENT OF SODA DEPOSIT IN EAST AFRICA

In a communication to the U. S. Bureau of Foreign and Domestic Commerce, Consul Henry P. Starrett at Mombasa, British East Africa, states:

A large deposit of raw crystalline soda at Lake Magadi, situated in the southern part of this protectorate, near the frontier of German East Africa, has attracted attention in recent years. This lake has an area of approximately 324 square miles and contains from 50,000,000 to 200,000,000 tons of sesquicarbonate of soda. On account of the existing soda springs in the lake, the supply is constantly being renewed, and it may therefore be said to be nearly inexhaustible. The raw material must be reduced to soda ash. Analysis of the product shows: Soda crystals, 98.55 per cent; salt, 0.20 per cent; sulphate of soda, 0.110 per cent; moisture and traces of impurities, 1.15 per cent.

About five years ago the Magadi Soda Co. (Ltd.), a British corporation, was formed to take over a 99-year lease of this deposit, with the company under the management of M. Samuel & Co., of London. In 1913 a branch railway line was constructed to connect the property with the Uganda Railway system, thus affording an outlet for shipments at the seaport of Kilindini.

May Resume Active Operations.

In 1914 the company expected to ship about 80,000 tons and gradually to increase the annual output until it reached 200,000 tons. Just at the time their plans were beginning to materialize, however, the war put a stop to operations. It is believed that active operations will be resumed just as soon as ocean freight rates become normal, or the market price of the product advances to a point which will warrant the payment of the present high shipping charges. The company has been granted a very favorable railway rate from the mines to the seacoast, enabling it to place the product aboard ship at Kilindini for about $4 per long ton. The ocean rate from Mombasa to New York via Durban or Liverpool is now about $39 per long ton (2,240 pounds).

[The London address of this company may be obtained from the Bureau of Foreign and Domestic Commerce, its district or cooperative offices. Refer to file No. 85677. Articles relating to the enterprise were published in Daily Consular and Trade Reports for March 9 and June 27, 1911, and September 26, 1913.]

MANUFACTURING TESTS OF COTTON FUMIGATED WITH HYDROCYANIC-ACID GAS

By

William S. Dean*

The Results of the Tests Described in the Following Paper Indicate That the Fumigation of Cotton with Hydrocyanic-Acid Gas Does Not Affect to Any Material Extent the Percentages of Waste, Spinning Qualities, Tensile Strength, Bleaching, Dyeing, or Mercerizing Properties of the Cotton.

INTRODUCTION.

The spinning tests herein described were suggested by a joint committee of cotton manufacturers and officials of the Federal Horticultural Board, who met and discussed plans of preventing the introduction into the United States of the pink boll worm[1] with the importations of foreign-grown cotton. As hydrocyanic-acid gas had been found by that Board to be a practicable and successful fumigating agent[2] in the destruction of these pests, even though the larvæ were in the center of a compressed bale of cotton, it was decided that manufacturing tests should be made to determine whether the fumigation by this agent would cause an injury to the cotton fibres.

SPINNING TESTS.

The manufacturing tests were conducted by the United States Department of Agriculture, under the direct supervision of the Office of Markets and Rural Organization. Through the courtesy of the president and manager the tests were made at the New Bedford Textile School, New Bedford, Mass., on two separate lots of cotton, a portion of each lot having been fumigated with hydrocyanic-acid gas under the supervision of the Federal Horticultural Board. In each lot the fumigated cotton was compared with nonfumigated cotton of the same lot.

The principal points taken into consideration during the spinning tests to determine whether the fibers were injured by the fumigation were (1) the percentage of waste, (2) the spinning qualities, (3) the tensile strength of the yarn. During the laboratory tests the following points were considered: (4) The bleaching properties of both the cotton and yarn, (5) the dyeing properties of the cotton and yarn, and (6) the mercerizing properties of the yarn.

In addition to the manufacturing tests, made by the Department of Agriculture, a number of manufacturing firms that regularly use foreign-grown cotton conducted tests in order to ascertain whether the fumigation of cotton with hydrocyanic-acid gas proved detrimental to their product. These tests were conducted in cooperation with officials of the Department of Agriculture.

Several manufacturing companies also sent yarns to Washington which were tested in the yarn testing laboratory of the Department of Agriculture for tensile strength. Two of these firms sent complete reports which included the comparative waste percentages of fumigated and nonfumigated cotton as found by them.

Stock of Cotton.

In the tests conducted by the Department of Agriculture the first lot consisted of two 50-pound samples, one taken from a fumigated bale and one from a nonfumigated bale. Both bales were of Sakellaridis Egyptian cotton 1¼ inch in length of staple. The fumigated bale was fumigated with hydrocyanic-acid gas on at least five dfferent occasions in a vacuum of 27 inches. The amount of sodium cyanide employed varied from 3 to 10 ounces per 100 cubic feet of chamber space with exposures ranging from thirty minutes to one hour. The volume of gas which penetrated this bale was fully ten times as much as that ordinarily used in accordance with the regulations prescribed by the Federal Horticultural Board. All other fumigated cotton referred to in this publication was exposed to hydrocyanic-acid gas in the presence of a 20-inch vacuum with 3 ounces of sodium cyanide per 100 cubic feet of chamber space with an exposure of one-half hour. The second lot consisted of 50-pound samples from each of six bales of Sakellaridis Egyptian cotton of 1½ inches in length of staple.

Three of the bales were fumigated and three bales were nonfumigated. In the selection of the fumigated and nonfumigated cotton a careful comparison was made of grade and staple in order to secure equal values.

A few samples of fumigated and nonfumigated Peruvian and Chinese cottons were secured from the mills and chemical laboratory tests were made on these cottons in the department of chemistry and dyeing of the New Bedford Textile School.

---

*Assistant in Cotton Testing, U. S. Department of Agriculture. From a Bulletin Issued by the Department.

[1] Hunter, W. D., The Pink Boll Worm. Unnumbered publication U. S. Department of Agriculture, Bureau of Entomology, August, 1914.

[2] For a description of this method of fumigation see U. S. Department of Agriculture, Federal Horticultural Board. Service and regulatory announcement No. 21, 1915.

Methods of Comparison.

Each bale was given a mark so that it could not readily be identified while in the manufacturing processes as to whether it had been fumigated. The fumigated and nonfumigated cottons of each lot were opened and left standing overnight. They were run through the machines under the same conditions of speeds and settings, and where possible the fumigated and nonfumigated portions of each lot were placed side by side on the same machine, advancing together through the various processes of manufacture. Between each run the machines were cleaned thoroughly. Total weights were taken before and after the cotton was fed into the opener, finisher, cards and combers respectively. Records of humidity were taken hourly and the humidifiers regulated accordingly, keeping the relative humidity as nearly uniform as possible for the respective lots.

Waste Percentages.

Table I gives the comparative waste percentages of the fumigated and nonfumigated cotton.

Lots No. 1 and No. 2 represent the 1¼-inch staple and the 1½-inch staple, fumigated and nonfumigated cotton given separately, which were tested at the New Bedford Textile School, New Bedford, Mass. Lots No. 3 and No. 4 represent a digest of the reports received from the two manufacturing firms.

TABLE I.—*Waste percentages.*

[Based on net weight of cotton fed into each machine.]

Kind of waste.	Lot No. 1.		Lot No. 2		Lot No. 3.		Lot No. 4.	
	Fumigated.	Nonfumigated.	Fumigated.	Nonfumigated.	Fumigated.	Nonfumigated.	Fumigated.	Nonfumigated.
Opener:								
Visible—								
Dust room	0.67	0.25	0.46	0.33	....	....	....	....
Motes and fly	1.06	1.50	.87	.67	....	....	1.45	1.47
Total visible	1.73	1.75	1.33	1.00	0.65	.53	1.45	1.47
Invisible	2.53	1.75	.29	.62	.83	.55	.05	.03
Total visible and invisible	4.26	3.50	1.62	1.62	1.48	1.08	1.50	1.50
Finisher:								
Visible—								
Dust room	.14	.14	.09	.09	....	....	....	....
Motes and fly	1.43	.96	.74	.05	....	....	.47	.48
Total visible	1.57	1.10	.83	.74	.78	.63	.47	.48
Invisible	.14	.13	.18	.04	1.15	.61	.03	.03
Total visible and invisible	1.43	1.23	1.01	78	1.93	1.21	.50	.51

The figures given in Table I are based on the net weight of stock fed into each machine. It will be observed that there is no decided indication of the superiority of either the fumigated or nonfumigated cotton. The percentages of waste fluctuate considerably, without being consistently in favor of either the fumigated or the nonfumigated stock. Similar differences would be expected to exist in the comparisons of any two bales of cotton selected for equal value.

Table II gives the total percentages of visible and invisible waste discarded by the respective waste-cleaning machines. The percentages here given are based on the net weight of cotton fed into the opener picker.

TABLE II.—*Visible, invisible, and total waste percentages.*

[Based on net weight of cotton fed into the opener picker.]

Kind of waste.	Lot No. 1		Lot No. 2.		Lot No. 3.		Lot No 4.	
	Fumigated.	Nonfumigated.	Fumigated.	Nonfumigated.	Fumigated.	Nonfumigated.	Fumigated.	Nonfumigated.
Total visible and invisible waste pickers	5.62	4.69	2.61	2.39	3.39	2.31	2.00	2.09
Total visible and invisible waste cards	6.51	7.20	7.23	7.12	11.28	11.03	6.75	8.09
Total visible and invisible waste combers	10.25	10.76	12 50	12.32	10.62	16.46	14.97	15.26
Grand total visible and invisible waste	22.48	22.65	22.34	21.83	25.29	29 80	22.72	25 25

There is no evidence of injury to the cotton indicated by the results of the visible and invisible persentages of waste discarded. In fact, Table II shows that in every case, except lot No. 3, the grand total waste discarded from the fumigated cotton was less than that discarded from the nonfumigated cotton. Should the results have been the reverse—that is, in favor of the nonfumigated cotton to the same extent—the effects of the fumigation might have been seriously questioned. However, since the two tests at the textile school do not disclose any material difference between these lots it is assumed that the differences shown by the mill tests are the result of technicalities.

Moisture Tests.

The results of these tests were substantiated by moisture tests of the fumigated and nonfumigated cotton at the textile school, shown in Table III. The results of these tests indicate that the fumigation had no appreciable effect on the absorptive properties of the cotton.

TABLE III.—*Percentages of moisture in the cotton while in the manufacturing processes*

Process.	Lot No. 2.		Difference.
	Fumigated.	Nonfumigated.	
Fed into opener	8.10	7.76	+0.34
Finished lap	8.09	7.66	+0.43
Card sliver	6.55	7.60	−1.05
Comber sliver	7.08	7.13	−0.05

Spinning Qualities.

The numbers of yarn made at the textile school to ascertain the spinning qualities were 40's and 50's from the 1¼-inch cotton and 10's, 20's, 30's, 40's, 50's, 60's, 80's, and 100's from the 1½-inch cotton. Close observations were made by the men who actually were running the machines and also by those supervising the work and no difference was observed in the general spinning qualities.

Tensile Strength.

In order to ascertain the tensile strength comparisons of the different lots of fumigated and nonfumigated cotton, a number of bobbins of the different numbers of yarn were sent from the textile school and the mills to the laboratory of the Office of Markets and Rural Organization of the Department of Agriculture for test purposes.

These tests were made by reeling off, in skeins of 120 yards each, the same numbers of yarn made from the different lots. The skeins were placed on racks (Method originated by Dr. N. A. Cobb of Plant Industry, U. S. Department of Agriculture.) in order to keep them separate and to avoid tangling, after which they were removed one at a time in rotation and broken with a power yarn-tester, the downward stroke of the traverser moving at the rate of approximately 12 inches per minute. Hourly humidity records were taken and the humidifier was regulated accordingly in order to maintain as nearly as possible a constant relative humidity of 65 per cent.

Table IV gives the results of the tensile-strength tests.

Lots Nos. 1 and 2, respectively, represent the two lots of 1¼-inch and 1½-inch Egyptian cotton manufactured at the textile school, while Nos. 3, 4, 5, 6, and 7 represent five lots of cotton, each manufactured by a different representative manufacturing company. The small variations in the various numbers of yarn were standardized for comparison. The differences in tensile strength, in some instances, were in favor of the fumigated and, in some instances, in favor of the nonfumigated cotton.

Table IV.—*Tensile strength comparisons*

(Made in Yarn Testing Laboratory of the United States Department of Agriculture.)

Number of yarn.	Lot No. 1.		Lot No. 2.		Lot No. 3.		Lot No. 4.		Lot No. 5		Lot No. 6.		Lot No. 7	
	Breaking strength in pounds per skein of 120 yards.		Breaking strength in pounds per skein of 120 yards.		Breaking strength in pounds per skein of 120 yards.		Breaking strength in pounds per skein of 120 yards.		Breaking strength in pounds per skein of 120 yards.		Breaking strength in pounds per skein of 120 yards.		Breaking strength in pounds per skein of 120 yards.	
	Fumigated.	Nonfumigated.	Fumigated.	Nonfumigated.	Fumigated.	Nonfumigated.	Fumigated.	Nonfumigated.	Fumigated	Nonfumigated.	Fumigated	Nonfumigated.	Fumigated.	Nonfumigated
15's					302.11	303.9								
20's													108.48	102.70
22's									102.30	100.45			115.38	115.48
40's	39.98	37.56												
50's	27.29	27.35												
55's							27.51	28.20						
75's											21.88	26.05		
80's			26.45	28.05										
84's							8.32	7.60						

It will be observed that in lot No. 3 the fumigated cotton produced the stronger yarn; in lot No. 4 the reverse was true.

Single-Thread Test.

In addition to the tests shown in Table IV several tests were made with a single-thread testing machine.[1] The results of these tests are shown in Table VI. The results of the single-thread tests are recorded in ounces, while the tensile strength in pounds per skein of the yarn taken from the same bobbins from which the single-thread tests were made is also given. In all cases where the skein tests are given in connection with the single thread tests, the yarn was taken from the same bobbins.

Table V.—*Tensile strength comparisons.*

[Made by two representative cotton mills.]

Number of yarn.	Lot No 3—Breaking strength in pounds per skein of 120 yards.		Lot No. 4—Breaking strength in pounds per skein of 120 yards.	
	Fumigated.	Nonfumigated.	Fumigated.	Nonfumigated
27's	114.8	112.8		
57's			30.25	30.60

The single-thread tests, judged from the comparative uniformity of breaks, did not disclose any superiority, either in the yarns made from the fumigated or from the nonfumigated cotton.

Table VI.—*Single-thread test*

[Made at the New Bedford Textile School.]

	Number of yarn.	Lot No. 1.		Lot No. 2	
		Fumigated.	Nonfumigated.	Fumigated.	Nonfumigated.
Ounces per single thread	40's	5.48	5.53		
Pounds per skein 60 yards	40's	49.3	46.9		
Ounces per single thread	30's			14.80	15.10
Pounds per skein 60 yards	30's			56.25	56.50
Ounces per single thread	60's 2-ply			16.58	16.41
Pounds per skein 60 yards	60's 2 ply			58.20	60.50

Two of the mills reported their findings as to the tensile strength of the cotton yarns they manufactured. These results are shown in Table V, under lots No. 3 and No. 4.

CHEMICAL LABORATORY TESTS.

Investigations also were made in the laboratory of the New Bedford Textile School[1] to ascertain whether cotton treated with hydrocyanic-acid gas lost any of its bleaching, dyeing, or mercerizing value. The following numerical designations represent the cotton and cotton yarns used in these laboratory tests:

KIND OF COTTON.

Sample
No.
1. 1¼-inch Sakellaridis Egyptian—fumigated.
1a. 1¼-inch Sakellaridis Egyptian—nonfumigated.
2. 1½-inch Sakellaridis Egyptian—fumigated.
2a. 1½-inch Sakellaridis Egyptian—nonfumigated.
8. Peruvian cotton, from center of bale—fumigated.
9. Peruvian cotton, from outside of bale—fumigated.
10. Peruvian cotton, from center of bale—nonfumigated
11. Peruvian cotton, from outside of bale—nonfumigated.
12. Peruvian cotton, from center of bale—fumigated.
13. Peruvian cotton, from outside of bale—fumigated.
14. Peruvian cotton, from center of bale—nonfumigated.
15. Peruvian cotton, from outside of bale—nonfumigated.

Samples 1 and 1a, respectively, represent the fumigated and non fumigated 1¼-inch sakellaridis Egyptian cotton, the two bales from which these samples were taken being previously referred to as lot No. 1. In a like manner 2 and 2a represent the 1½-inch fumigated and nonfumigated cotton previously referred to as lot No. 2. Samples 8 to 15, inclusive, were selected from Peruvian cotton received from a manufacturing company. The cotton in samples 1, 2, 8, 9, 12, and 13 was fumigated with hydrocyanic-acid gas.

---

[1] These strength tests were made by William Smith, professor in charge of the Carding and Spinning Department of the New Bedford Textile School, New Bedford, Mass.

[1] These tests were made by Everett Hinckley, professor in charge of the Department of Chemistry and Dyeing, New Bedford Textile School, New Bedford, Mass.

Bleaching of Raw Cotton.

Samples of Nos. 2 and 2a were bleached by treating as follows:

Method *a*. Not scoured. Bleached with a solution obtained by the electrolysis of salt containing 0.5 gram of chlorine per liter. In future this solution will be designated as "electrolytic chlorine."

Method *b*. Scoured in a solution containing 1 gram of soda ash in each 10 cc. then bleached as in *a*.

Method *c*. Treated with 2 per cent. acetic acid and bleached as in *a*.

Finally all the samples were blued with 0.001 per cent. of blue-violet acid dye.

Methods *a*, *b*, and *c* are the usual processes for obtaining white cotton for spinning except that the usual quantity of bleaching agent used was reduced in these tests in order to magnify any variation in the results obtained. No differences in the results of any of the methods on the two samples were apparent, which indicates fumigating the cotton with hydrocyanic-acid gas had no appreciable effect upon the bleaching qualities of the cotton used in any of the tests.

To test the effect of fumigation on the various bleaching agents commonly used the following tests were carried out on samples No. 2, 2a, and 8 to 15, inclusive:

Method *d*. The cotton was boiled two hours in a 10 per cent. solution of soda ash and bleached cold in "electrolytic chlorine" containing 2 grams of Chlorine per liter.

Method *e*. The cotton was treated as in *d* except that chloride of lime solution containg 8 grams of chlorine per liter was used as the bleaching agent.

Method *f*. The cotton was treated as in *d* except that an alkaline solution of sodium peroxide equivalent to 15 grams of chlorine per liter was used. After bleaching all of the samples were blued as in methods *a*, *b*, and *c*.

The concentrations of bleaching agent are similar to those used in practice to obtain equal bleaching value. Close examinations were made of the samples by constructing a sample sheet with the different samples placed thereon for comparison. This comparison gave no indication that fumigation of cotton alters the bleaching value.

All of these tests were carried out on all of the samples of cotton.

To confirm these results, five 1-pound samples of Nos. 2 and 2a were treated by method *d*, the following details being observed in connection with the bleaching: After scouring, the cotton was rinsed 30 minutes in cold water, squeezed, and treated 2.5 hours cold with "electrolytic chlorine," 1.46 grams of chlorine per liter; was rinsed well, treated 30 minutes in a 5 per cent. solution bisulphite of soda, cold; was rinsed well, and blued with a solution containing three-fourths of a gram vat blue in 10 liters of water.

Samples 10, 11, 14, and 15 were combined into one lot, samples 8 and 9 into a second lot, and samples 12 and 13 into a third lot, and each lot was bleached by the method outlined in the previous paragraph for samples Nos. 2 and 2a.

By comparison of these samples it was evident that there was as much difference in bleaching quality between the two bales of nonfumigated cotton as there was between the bales of fumigated and nonfumigated cotton of the same quality.

Description of Further Test.

Samples of fumigated and nonfumigated Chinese cotton which had been both bleached and blued by a representative cotton mill were submited for examination. As a result of the bluing process, the sample of fumigated cotton was a more intense blue than the sample of nonfumigated cotton. On receipt, tests were made on these samples for iron to ascertain if there had been a formation of Prussian blue, due to the presence of hydrocyanic acid in the fumigated cotton, which would cause the intensifying of the color of the cotton. Negative results were obtained. The bluing matter was extracted with water until the samples were practically the same color. These water extracts were of different depths of blue. The deepest extract was then diluted until both were of the same shade of blue. The extracted cotton samples were treated again in their respective solutions. The resultant samples were of the same color.

From the above results the conclusion was reached that the increased depth of blue on the fumigated sample was because it had been treated with a greater quantity of bluing and not because of the presence of hydrocyanic acid or because of any chemical change in the fiber such as the formation of hydrocellulose.

Test for the Presence of Hydrocyanic Acid.

Small specimens from each of the following samples, 2, 2a, and 8 to 15 inclusive were tested for the presence of hydrocyanic acid as follows:

The sample was covered with a solution of 10 c. c. of distilled water, 5 drops concentrated sulphuric acid, 5 c. c. 2/normal ferrous sulphate and 6 c. c. normal solium hydroxide heated nearly to a boil then 5 c. c. 6/normal hydrochloric acid were added.

These tests gave no blue coloration which indicated the absence of hydrocyanic acid in all of the samples at the time of treatment.

Bleaching of Yarns.

The material used in these bleaching tests consisted of yarn made from the following samples of cotton: 1 and 1a, 2 and 2a. Samples 1 and 2 had been fumigated, and samples 1a and 2a were nonfumigated.

All four samples were treated as follows: Boiled for two hours in 10 per cent. solution of soda ash at atmospheric pressure, rinsed until free from alkali, then divided into two lots, each lot containing one-half of each of the above four samples. One lot was bleached by method A, the other by method B, as follows:

Method A. Treated cold for two hours in a 2° twaddle solution of bleaching powder, containing 5.82 grams of chlorine per liter, rinsed with cold water, soured with 2 per cent. solution of acetic acid, rinsed and antichlored in a 2 per cent. solution of sodium bisulphite 30 minutes, then finally rinsed and blued in water containing 1 gram of vat blue in each 13 1/3 liters.

Method B. Treated as in method A, except that a solution of electrolized salt containg 2.87 grams per liter of available chlorine was used as the bleaching agent.

The tensile strength and the number of the yarn of all four samples were taken before and after treatment with bleach A and beach B with the results as shown in Table VII.

Table VII.—*Tensile strength of yarns before and after bleaching.*

Sample No.	Grey			Bleach A			Bleach B.		
	No of yarn.	Skein breakage, 60 yards	Single-thread breakage	No of yarn.	Skein breakage, 60 yards.	Single-thread breakage.	No. of yarn	Skein breakage, 60 yards.	Single-thread breakage
1	26.4	44.8	10.9	29.2	36.8	8.7	29.1	14.1	10.4
1a	26.4	45.7	10.9	29.2	39.4	8.9	29.4	43.8	9.7
2	41.5	42.4	9.8	47.2	7.7	7.9	46.5	34.6	8.9
2a	41.5	43.2	9.8	47.2	29.3	8.0	46.5	39.0	9.1

In this table the tensile strength[1] is given in pounds for the skein breaks and in ounces for the single-thread breaks. The skeins were taken from the same bobbins of which the single threads were tested. From the comparisons of these figures it will be seen that the differences in strength between the fumigated and nonfumigated cotton are so small that it would be unsafe to say that these yarns contained in them any substance such as acids that would reduce the tensile strength of the yarn by releasing the bleaching agent too rapidly.

Dyeing of Yarns.

Portions from all of the four samples of yarns, namely, 1, 1a, 2, and 2a, were bleached according to method A and method B, except that they were not blued. Instead some of the portions were dyed pink and some were dyed blue with both direct and basic dyes.

Direct Dyes.

Method of application.—Dyed in a bath containing 0.1 per cent. benzo rhoduline red B, 5 per cent. of salt, 0.5 per cent. soluble oil. Volume of dye bath equals 25 times the weight of the goods. The goods were entered into the dye bath cold and temperature raised to a boil in 30 minutes, boiled 15 minutes, and allowed to cool in the bath 15 minutes. To obtain the light blue the goods were dyed in the same manner, except 0.1 per cent. benzo fast blue BN was used instead of the benzo rhoduline red B.

Basic Dyes.

Method of application.—Mordanted in a solution containing 0.015 of a gram of tannic acid in each 100 cc. The goods were entered into the dye bath cold and temperature raised to 190° in 45 minutes, then allowed to cool overnight, rinsed and treated cold for 15 minutes in a bath containing 0.01 of a gram of tartar emetic.

The pinks were dyed in a bath containing 0.05 per cent. of rhoduline red B, 0.5 per cent. of acetic acid, cold 30 minutes, then raised to 140° during 30 minutes. The blues were dyed as the pinks, except that 0.05 per cent. of methylene blue BB was used.

No practical difference was seen between the whites obtained on samples 1 and 1a or on 2 and 2a, respectively, where the same bleaching agent was used. Nor could it be seen that the fumigation had made the cotton either more easy to dye or more difficult to dye with direct or basic dyes.

Mercerizing of Yarns.

Samples of yarn made of each of the above four cottons, namely, 1, 1a, 2, and 2a, were mercerized by commercial methods at one of the mills in New Bedford, Mass., and these samples were subsequently tested for their tensile strength and degree of mercerization. In Table VIII the results of the average number of the yarn and tensile strengths, ascertained before and after mercerization, are shown.

Table VIII.—*Tensile-strength tests of natural gray and mercerized yarns.*

Sample.	Natural gray			Mercerized.		
	No. of yarn.	Strength in pounds per skein of 60 yards.	Strength in ounces per single thread.	No. of yarn.	Strength in pounds per skein of 60 yards.	Strength in ounces per single thread.
1	20.84	58.6	13.8	22.0	70.0	20.2
1a	20.84	59.9	13.9	22.0	71.2	21.0
2	30.5	56.0	15.0	30.7	66.0	19.9
2a	30.6	58.5	15.2	30.7	68.1	20.2

From Table VIII it will be seen that the gain in tensile strength due to mercerization is a trifle greater for the nonfumigated than for the fumigated cotton.

The tests for the degree of mercerization were made by dyeing samples of the fumigated and nonfumigated mercerized yarns in 1 per cent. benzo purpurin 4 B, 10 per cent. salt, 1 per cent. soluble oil, 30 minutes at 160°, volume of bath equal to 100 times the weight of goods treated. The same weight samples of mercerized Egyptian yarn were dyed in the same bath after dyeing the fumigated and nonfumigated samples. These exhaust skeins furnished a means of measuring the degree of mercerization, for the better mercerized samples absorb more dyestuff and consequently leave less in the dye bath. In order to ascertain more accurately the degree of mercerization, a sheet of samples was prepared by dyeing mercerized Egyptian cotton with the percentages of dyestuffs shown in Table IX. Salt and soluble oil was used as in method given above, benzo purpurin 4 B being used as the dyestuff.

---

[1] Tests made by Professor Smith.

TABLE IX.—*A set of color standards.*

Standard No.	1	2	3	4	5	6	7	8	9
Dye, per cent	5	4.5	4	3.5	3	2.5	2	1.5	1
Salt, per cent	20	20	20	20	20	20	10	10	10
Soluble oil, per cent	2	2	2	2	2	2	1	1	1
Standard No.	10	11	12	13	14	15	16	17	18
Dye, per cent	0.9	0.8	0.7	0.6	0.5	0.4	0.3	0.2	0.1
Salt, per cent	10	10	10	10	10	10	10	10	10
Soluble oil, per cent	1	1	1	1	1	1	1	1	1
Standard No.	19	20	21	22	23	24	25	26	27
Dye, per cent	0.09	0.08	0.07	0.06	0.05	0.04	0.03	0.02	0.01
Salt, per cent	10	10	10	10	10	10	10	10	10
Soluble oil, per cent	1	1	1	1	1	1	1	1	1

The samples of colored yarns obtained by dyeing in the exhaust bath were matched against the standards, and it was found that cotton No. 2a (nonfumigated 1½-inch Egyptian cotton) dyed a lighter shade, indicating a greater degree of mercerization than cotton No. 2 (fumigated 1½-inch Egyptian cotton). But results from lots 1 and 1a fumigated and nonfumigated, respectively, were practically identical.

Conclusion.

The results of these tests indicate that the fumigation of cotton with hydrocyanic-acid gas does not affect, to any material extent, the percentages of waste, spinning qualities, tensile strength, bleaching, dyeing, or mercerizing properties of the cotton.

PURE OXIDE OF URANIUM PREPARED BY NEW METHOD

For a process for the purifying of uranium compounds and for a process for preparing oxides of uranium, two patents have been granted to Charles L. Parsons, Chief Chemist of the U. S. Bureau of Mines. These patents have been dedicated for the free use of the people.

The process for the preparing of uranium oxide is of special importance at this time owing to the fact that it is now definitely known that the Germans are using uranium steel in some of their large cannon, and this process will enable pure black oxide of uranium to be obtained for the use of producing ferro-uranium. Experiments in the production of uranium steel itself are now under way. By the use of the process above mentioned the production of pure oxide of uranium is very much facilitated and cheapened. Also the product is obtained in a much purer form than has ever been acquired heretofore. Uranium oxide so obtained is also valuable for coloring glass, giving to glass the golden yellow color seen in some of the newer forms of automobile headlights. In connection with the uranium work of the bureau, considerable quantities of uranium were produced, and the methods here referred to permit this to be converted into useful forms of commerce.

GOVERNMENT REPORT ON SHALES YIELDING PETROLEUM

The gasoline engine has now become so essential in manufacturing and in transportation that the possible early exhaustion of our natural supply of petroleum, the primary source of the "gas," has become a "burning question," and any data regarding substitutes and possible sources of supply are sought with great interest. Bulletin 641-L of the United States Geological Survey, Department of the Interior, on the "Oil Resources of Black Shales of the Eastern United States," by George H. Ashley, just published, gives information showing the richness and distribution of certain shales, which on distillation will yield oil, gas and ammonia. The report gives the results of tests by the Bureau of Mines of samples of Devonian and Carboniferous shales collected by the Survey geologists at 42 localities in seven States east of the Mississippi, and a rough estimate of the quantity of oil that may be obtained by the distillation of the available shale in a part of this area. The yield of oil from most of the samples examined was small, averaging about 10 gallons per ton of shale—a yield too low for commercial extraction under conditions likely to arise in the near future. Nevertheless the deposits are of interest as indicating the wide extent of shales of this character. The richer beds may possibly be utilized in the future in ways or through processes not now foreseen.

A copy of Bulletin 641-L may be had free of charge on application to the Director of the United State Geological Survey, Washington, D. C.

Adamson to Represent Maritime Corporation.

Announcement has been made by the Maritime Coaling Corporation, of Wilmington, Del., chemicals, etc., of the appointment of P. Chauncey Adamson, 25 Broad Street, Manhattan, as their representative in the State of New York.

International Chemical Co.

The International Chemical Company of Seattle has been incorporated with a capital of $15,000. Will deal in salt cake, anhydrous soda sulphate, glauber's salts, silicate of soda, sulphate of potash, kieselguhe, etc. The incorporators are P. D. Donaldson, H. B. Brown, Alex Neven, Day Karr, G. W. Gregory.

THE COAL TAR DYESTUFF INDUSTRY

I. F. Stone.

Its Development and Permanency in the United States

By I. F. Stone*

In the Accompanying Article, Mr. Stone Shows That, Thanks to Factories Capable of Producing the Colors Necessary for Consumption, an Adequate Tariff Protection by the Government, a Strong Financial Condition Established During the War, and the Preference of American Consumers for American Products, We have Made Certain Both the Development and Permanency of the American Dyestuff Industry.

Before entering upon a discussion of this subject it will be well to consider beforehand a brief sketch of the history of the coal tar dyestuffs industry from the time of its inception in this country. The first American aniline factories were established about 1875. By 1880 there were some ten factories engaged in the manufacture of these products, and it looked as though the industry would be highly successful, for tariff conditions at that time were favorable to this form of enterprise.

Unfortunately, however, a new tariff law was passed three years later which reduced the protection on colors to such an extent that a profitable maintenance of the industry was no longer possible. As a consequence, most of the factories ceased all production until at one time there were only three engaged in this manufacture. The operation of these three was continued by their owners in the hope that some day conditions would change for the better, rather than for immediate gain, and one of the factories actually lost a large amount of money before it finally reached success in about 1900.

About 1898 another factory was established, and 1914 saw the establishment of still another, so that in the latter year, at the beginning of the present European war, there were five factories actively engaged in this industry. Owing, however, to the intense competition of the European manufacturers, especially the Germans, none of these factories were successful enough to make a complete line of colors, and were restricted to the production of only a few of those which could be made to advantage in this country. Therefore the industry was not a large one and was not running to any considerable extent.

Hampered By Lack of Domestic Intermediates.

One reason why the industry could not operate successfully was the lack of what we call intermediate products, that is, products made from benzole and naphthalene (coal tar derivatives) which are the bases of the manufacturing of practically all aniline colors. With one exception, which I will mention later, none of these intermediate products were manufactured in this country up to 1914, when the war began.

The American manufacturers were therefore obliged to rely entirely upon European factories for their raw materials—in other words, the intermediate products—and naturally, the European manufacturers charged them such a price that they could not successfully compete with the finished colors of Europe, which were made from the same intermediate products, but which were, of course, secured by the European manufacturers at a lower price than they could be secured by the American manufacturers who imported them.

The single exception to this statement is that in 1910 a factory for the manufacture of one of the intermediates, viz,: aniline oil, was established, but had not been at all successful up to the time of the war, owing to European competition, the European manufacturers, by the way, having reduced their price immediately upon the establishment of this American factory.

Situation Becomes Acute.

The situation was then, in 1914, when the war began, that no intermediate raw materials were manufacturd here with the exception of this comparatively small amount of aniline oil. Then the supplies of these intermediate products from European factories, that is, German factories, were immediately cut off, just as were the supplies of the finished aniline colors, and the American manufacturers therefore were not able to relieve the situation except to the extent of using up what raw materials they had on hand, which, of course, were not nearly enough to be of any perceptible help to the consumers of aniline dyes.

A few months after the war started, say about January 1, 1915, the situation had become very acute, as practically all the stocks of imported colors which were here at the beginning of the war had been consumed, as had also the raw materials employed by the American factories in their manufacture of colors, the one exception being a factory which had previously been receiving its aniline oil from the American manufacturer, and therefore it was enabled to continue this manufacture of colors without any particular interruption, except the interruption of the lack of foreign intermediates, of which, however, it fortunately had a large stock.

---

*President of the National Aniline and Chemical Company, vice president of the Schoellkopf Aniline and Chemical Works, Inc.

I am not mentioning names of any of these factories in this article as I wish to be absolutely impersonal, but there is no question but that the position of this factory just mentioned, with its supply of raw materials, was a great relief to the consumers of dyes in this country, and it was very fortunate for them that a factory had been established for the manufacture of aniline oil, and that as American manufacturers of colors they had taken the precaution to secure their supply from this American factory, even though they were obliged to pay a higher price than they could have imported the oil for at the time. They preferred, however, to do this in order to encourage the American manufacturers of these intermediate products.

Very soon after the war began, however, it became apparent that there would be a great necessity for the manufacture of these intermediate products in this country, and as the basic material, that is, coal tar, is of course a large domestic product, it was then only necessary to recover its derivatives, such as benzole and naphthalene, and benzole, being particularly needed for explosives and other war purposes, was the first product which had the attention of the American producers.

Production of Benzole Increased.

The production was increased gradually until it has reached at the present time something like 30,000,000 gallons annually as against about 3,000,000 gallons prior to the war, and the production of naphthalene has also increased largely owing to its demand for use as a raw material in the manufacture of these intermediates, although not to such an extent as benzole.

The manufacture of intermediates gradually increased to such an extent that there are now being manufactured a large variety, such as alpha-naphtylamins, beta-naphtol, benzaldehyde, benzyl acetate, chlor-benzole, dimethylaniline, di-nitro-benzole, di-nitro-phenol, nitro benzole, paranitraniline, paraphenylene-diamine, toluidine and others too numerous to mention, so that American manufacturers of colors are now able to get a fair supply of these intermediates, and therefore are enabled to make a more complete line of colors than was possible at the outbreak of the war.

As I have previously mentioned, the first large intermediate to be manufactured, however, was aniline oil, the factory which originally manufactured it before the war immediately increasing its production, and many other concerns starting in later on until it came to a point where the production was fully if not more than equal to the demand, and the fact is, that factories making this product are in such a strong position that it is doubtful whether it will ever again be imported from Europe to advantage.

Another intermediate, the manufacture of which was commenced largely, was chlor-benzole, which is used in the manufacture of sulphur black, a very important color for cotton goods, and for which there is a large sale. The manufacture of this color, by the way, is now so large that it is fully equal to the consumption, and is another product which will probably never be imported again to advantage. Other intermediates followed-until, as I have said, at present we are able to obtain sufficient variety to manufacture a line of colors which will probably take care of the necessary shades, which includes blacks, blues, browns, reds, yellows, greens, orange, violet; the seven primary colors, from mixtures of which practically every shade can be obtained for all materials such as wool, cotton and silk.

An Abundance of Blacks.

It has been stated that American manufacturers are not on a firm basis for the reason that they followed the lines of the least resistance in making colors, that is, made the colors which were easiest to manufacture, and that when the war is over and competition comes again from Europe they will not be able to stand against it. This opinion is not true, in that while it is true that they did follow the lines of least resistance, it so happened that the colors manufactured were the ones most largely consumed, such as blacks, for instance. This is by far the color most largely consumed, being practically half of the entire color consumption of the country, and this was the first color to receive attention of the American manufacturers, it being obvious that a color which could be manufactured in large quantities would mean a less cost for overhead expenses.

Therefore there is now an abundance of blacks made for all purposes, sufficient to take care of the whole consumption of the country, for instance:—Direct blacks for cotton, union, wool and silk, azo black or acid black for wool and silk, sulphur black for cotton (already mentioned), chrome blacks for wool, and nigrosines for leather, inks, etc., so that this particular color is very well taken care of.

Consumers can get the necessary quantity for consumption next year if they were careful to contract for same in time to allow the American manufacturers to arrange their facilities and buy the raw materials necessary to take care of such contracts for 1917.

The next color in importance, which had their attention, was blue, this being next to black in the proportion of consumption. They are now producing blues for the same textiles, viz: wool, cotton and silk, to a very satisfactory extent.

All Necessary Shades Produced.

The production of other colors has followed in the order of their importance, so that now practically all shades are produced. To illustrate clearly the rapid development of this industry, I would point out that whereas there were only five factories making aniline dyes in the United States prior to the fall of 1914, when the war began, we now have a total of about 120 making intermediates and anilines, and, as I have stated above, their whole production will take care of the entire country as far as the necessary colors are concerned.

Special colors, although not now manufactured in this country, such as Indigo, vat colors and some specialties for particular purposes, are in prospect, and it is, I believe, only a question of a comparatively short time when a complete line will be manufactured here.

It being a fact that the American manufacturers are now able to produce all of the necessary colors, needed, the question, then, is whether this will be a permanent industry or whether the conditions which prevailed before the present war will again be the same—that the European manufacturers may be able to flood the country with their colors at prices with which the American manufacturer cannot compete. It gives me much pleasure to be able to answer this question very definitely in the affirmative, viz: the dyestuff industry in this country is now on a permanent basis for the following reasons:

Industry Firmly Established.

First—The production of coal tar derivatives, like benzol and naphthaline, has been increased to such an extent that the quantities produced are now from ten to twenty times more than before the war, and the manufacturers of intermediates, depending on these products, will continue to be able to get a full supply of them at prices which will compare favorably to European prices on account of this largely increased production, it being well known that the United States has practically inexhaustible supplies of coal, which is the base product, and from which will be derived the benzol and naphthaline and other products necessary for the manufacture of the intermediates which, in turn, produce the finished colors.

Second—The United States Government has finally discovered that in order to make this industry permanent it is necessary to give more adequate tariff protection; therefore a tariff bill, known as H. R. 16763, was passed in 1916 giving a protection of 30% ad valorem and 5c per pound specific duty on finished colors, and 15% ad valorem and 2½c. per pound specific duty on intermediates,—the addition to the old tariff being the 5c. and 2½c. per pound specific duties just mentioned, and this additional protection gives the American manufacturers a very much better opportunity to operate, although, even at that, a higher protection would be still more important if it could be obtained. The exception to the above protection is that on indigo, and on what are known as indigoids and alizarine colors, no specific duty was imposed, although they were given the 30% ad valorem duty as against the fact that they were free before this bill was passed. There is no specific reason why these colors should not also have this specific duty and why they were excepted in the passing of this bill is a question for those who passed it to answer, but I believe that upon mature consideration this exception will be canceled and all of the colors now manufactured in this country will have the same protection.

Third—The manufacturers of intermediates and colors have, during the war, been able to obtain, owing to abnormal conditions, an abnormal rate of profit, and out of this abnormal profit they have been able to build and pay for their factories as well as accumulate a surplus profit which they can use for the further increase of their present production and the working out of the special colors not manufactured here at present.

Fourth—The American consumers have realized, due to the conditions prevailing since the war, the importance of having an aniline industry in this country which will in the future prevent a repetition of the conditions which prevailed just after the war began, when it was for some time impossible to secure enough colors for the consumption of the country, and as a consequence of which many consumers were obliged either to run their mills or factories only a part of the time, or, as in some cases, close down entirely. With this realization, therefore, they will undoubtedly give the preference to American made products, which, in itself, would help in the competition against European manufacturers after the war.

To sum up briefly the whole question of the development and permanency of the coal tar dyestuff manufacturing industry in the United States, it is apparent from the above that with factories capable of producing the colors necessary for consumption, an adequate tariff protection by the Government, a strong financial condition established during the war, and the preference of American consumers for American products, we have certainly insured both the development and permanency of the American dyestuff industry.

Special Research Study for Professors Rose and Trumbull.

Beginning about June, one year of research study on tanning and various phases of physical chemistry will be spent at the Mellon Institute of Industrial Research, Pittsburg, Pa., by Professors Robert E. Rose and Harlan L. Trumbull, of the University of Washington.

ELECTROCHEMISTS HOLD THIRTY-FIRST GENERAL GATHERING IN DETROIT

Attended by nearly 200 members from various parts of the country, the thirty-first general meeting of the American Electrochemical Society, held in Detroit from Wednesday, May 2, to Saturday, May 5, proved to be one of the most successful in the history of the organization. In all, four technical sessions were held, as well as the annual business meeting. The former saw the presentation of an unusually large number of excellent papers, many of which are published in full or in abstract in the current issue of "Metallurgical and Chemical Engineering." The social and semi-social events included visits to the Dodge, Ford and Packard automobile factories; visits to the electric steel plants of the Michigan Steel Castings Co. and the John A. Crowley Co.; a whitefish dinner at the "West Wood," a theatre party, and, most notable of all, a smoker on the roof garden of the Hotel Tuller. The latter gathering brought forward much poetical and histrionic talent which achieved its greatest triumph in the production of a play entitled "Research in Hell, A Futurist Impression of Mephistopheles' Research Laboratory" which was rapturously received.

DR. COLIN G. FINK.
[Courtesy of "Metallurgical and Chemical Engineering."]

Officers For the Coming Year.

At the business meeting, held Thursday morning in the ballroom of the Hotel Statler, officers were elected as follows:

President, Dr. Colin G. Fink, head of the Research Laboratory of the Edison Lamp Works, General Electric Company, Harrison, N. J.; vice-presidents, H. C. Parmelee, Dr. F. C. Frary, and John Wood Beckman; managers, L. E. Saunders, Dr. John A. Mathews and A. T. Minckley, and treasurer, Pedro G. Salom. Dr. Joseph W. Richards was re-elected secretary.

Dr. Fink, the new president, who succeeds Francis A. J. Fitzgerald, graduated from Columbia University in 1903, following which he spent four years in the Otswald laboratory at Leipzig, where he acquired his doctor's degree. He is chiefly known for his discovery of "ductile" tungsten, while one of the important products of his laboratory is the platinum substitute leading-in wire, which consists of a compound copper or cobalt wire with a corrected expansion coefficient, and which resulted in the conservation of platinum to the extent of millions of dollars annually.

The fall meeting of the Society will be held from Wednesday, October 3, to Saturday, October 6, in Pittsburgh.

Original Papers.

Among the original papers presented during the four technical sessions, the following are included:

"Comments on the Electric Steel Industry," by Dr. John A. Mathews, president of the Halcomb Steel Co., Syracuse, N. Y.

"The Electric Furnace in the Steel Casting Plant," by R. F. Flinterman, president of the Michigan Steel Castings Co., Detroit, Mich.

"Notes on Electric Steel Melting," by J. L. Dixon, of the John A. Crowley Co., Detroit, Mich.

"A Description of the Bethlehem 10-Ton Girod Steel Furnace," by C. A. Buck, of the Bethlehem Steel Co., South Bethlehem, Pa.

"Electric Characteristics of Electric Furnaces," by A. A. Meyer, of the Detroit Edison Co.

"Improvements in the Rennerfelt Electric Furnace," by C. H. vom Baur, associated with Messrs. Hamilton and Hansell.

"The Grinding Wheel—A Connecting Link Between the Electric Furnace and the Automobile," by R. G. Williams.

"Chemistry of the Flaming Arc in Relation to Luminescence," by William Roy Mott, of the National Carbon Co.

"The Vosmaer Phenomenon," by Dr. W. C. Moore.

"Acid-Resisting Properties of Some Iron-Silicon Alloys," by Prof. O. L. Kowalke, of the University of Wisconsin.

"Low-Temperature Electrothermal Processes," by C. F. Hirshfeld, chief of the Research Department of the Detroit Edison Co.

"The Current Efficiency in Charging the Edison Storage Battery," by Dr. M. De Kay Thompson and L. R. Byrne of the Massachuetts Institute of Technology.

(Continued on Page Following)

"Magnetite Electrodes," by Dr. M. De Kay Thompson and T. C. Atchison.

"Electrolytic Pickling of Steel," by Dr. M. De Kay Thompson and O. L. Mahlman, Massachusetts Institute of Technology.

"Tests of Antimony Plating Baths," by Dr. F. C. Mathers and K. S. Means, Indiana University.

"Electrodeposition of Antimony from Fluoride Baths Containing Addition Agents," by Dr. F. C. Mathers, K. S. Means and B. F. Richard.

"Addition Agents in the Electrodeposition of Silver from Uncommon Silver Salts," by Dr. F. C. Mathers and T. G. Blue.

"Essential Oils as Addition Agents in Plating Baths," by Dr. F. C. Mathers and A. B. Leible.

"Electrical Endosmose and Adsorption," by Drs. T. R. Briggs, H. L. Pierson and H. S. Bennett, of Cornell University.

"A Cuprous Oxide Photochemical Cell," by Theodore W. Case, of Auburn, N. Y.

LALANG GRASS AS A NEW SOURCE OF PAPER PULP

From the Indian Trade Journal comes information relative to recent experiments of interest to chemists engaged in the paper industry. The article, reprinted in the U. S. Government's Daily Commerce Reports, follows:

A well-known agricultural and technical chemist in Queensland has conducted very successful experiments in manufacturing paper pulp out of lalang grass, or, as it is more commonly known, blady grass, on account of its great blades which are 4 or 5 feet long. It resembles very closely the esparto of Spain and North Africa, and when dried before making it into pulp yields as high as 60 per cent. of first-class paper-making pulp.

The expert states that esparto is the best pulp known and the blady-grass product is within 10 per cent. of the same value. There are millions of tons of this grass growing in Queensland. Three crops a year can be cut from it, and it is a curse to the country. He is also experimenting with other plants with good results, namely Chinese barr (*Urena*) and the Queensland hemp (*Sida Retusa*). They produce 30 per cent. of first-class paper pulp. Lantana, which is also regarded as a great pest, makes an excellent wrapping paper. Screwpine or pandanus, which also grows prolifically, is likewise being experimented with.

LEEDS CHEMICAL FIRM BUYS COAL-TAR PLANT

According to advices received by the U. S. Bureau of Foreign and Domestic Commerce, Brotherton & Co. (Ltd.), of Leeds, a firm which manufactures ammonia and coal-tar products, has announced the purchase of the Mersey Chemical Works, built by the Badische Aniline & Soda Febrick at Bromborough Port, Dirkenhead, near Liverpool, for the manufacture of aniline dyes. These works were sold at auction in the winding up of alien enemy concerns in this country, and the price paid is given as £135,000 ($656,977). The head of the firm is quoted by the Yorkshire Evening Post, of Leeds, as stating that when the present extraordinary demand for high explosives has ceased, plant and material will go to a considerable extent to the manufacture of coal-tar intermediate products and dyes.

Brotherton & Co. (Ltd) controls works established in chronological order as follows: Leeds, 1882; Stourton, 1888; Birmingham, 1893; Liverpool, 1904; Glasgow, 1904; Sunderland, 1905; Workington, 1913; and Middlesborough, 1913.

REFRACTORIES AND GLASS MIXTURES BEING STUDIED

Investigations of silica brick, graphite crucibles, and glass mixtures are among the branches of scientific work conducted at the United States Bureau of Standards recently with the object of aiding American industries. Some of these tests were in continuation of work which has been progressing from month to month.

In the study of silica brick special attention was paid to the development of a test which will serve readily to determine the quality of this class of brick. Samples are being collected from very widely distributed districts for the purpose of investigating the quality of the brick as furnished. This will supplement work already completed upon which a report is being prepared. The changes that take place in the quarzite used in making this material have been followed microscopically. The bureau prepared 109 specimens. Three burnings were made, totaling 216 pieces, and many volume determinations were made

Use of Natural and Artificial Graphite.

In the study of graphite crucibles, nine different mixtures were used in which there were both natural and artificial graphite. The artificial graphites were those made in both electric furnaces and blast furnaces. The study of the loss of carbon by oxidation, while burning, was continued, and a boxlike specimen of the graphite clay mixtures was prepared, to be used in studying the behavior of these during burning.

At the Bureau's Pittsburgh laboratory three melts were made of boro-silicate glass mixtures, and a mixture was melted giving a light barium crown glass. The latter melt was largely for the purpose of trying out the large kiln. It has been found to heat up in a fairly satisfactory manner, and it is believed that with the use of the large pots and large batches, satisfactory results will be obtained in this furnace. The large pots have been delivered and a melt started which will produce about 500 pounds of glass.

CHEMICAL INVESTIGATION
EFFICIENCY & CONTROL

CONDUCTED BY CHARLES B. DAVIS, F.C.S.

ALL classes of work covered by the following subjects will be done for readers of "The Chemical Engineer" through this department by Mr. Davis: Special research of every description; analysis and reproduction of any commercial product; prevention of waste and utilization of by-products on the most economical basis; valuation of raw materials; food analysis, and disputed points in regard to adulteration, labeling, and the enforcement of pure food laws; bacteriological and enzymatic examinations, including fermentation tests, pure yeast cultures, beverages of all kinds; development of chemical inventions and industrial processes; examinations and advice on special machinery.

Inquiries of a minor character will be answered on this page, while major matters involving personal investigations, analyses, etc., will, if desired, be treated confidentially through the mails. All questions, materials for analysis, or letters leading to the opening of negotiations for special work will receive prompt attention if addressed to

CHARLES B. DAVIS,
Care of "The Chemical Engineer," 118 East 28th Street,
New York City.

G. S. K.—According to the Chilean Government there is still sufficient unmined nitrate of soda (Saltpeter) in Chile to last another two hundred years. The quantity in the examined ground is:—

	Tons.
Province of Tarapaca	35,000,000
Tocopilla District	28,000,000
Antofagasta (Central)	32,000,000
Antofagasta (Aguas Blancas Dist.)	49,000,000
Taltal	95,000,000
Chanaral & Copiapo	8,300,000
	247,300,000

C. E. B.—The dry residue obtained from the activated sludge process of sewage purification has the following composition:—

Loss on ignition	70.4%
Mineral matter	29.6%
	100.0%
Nitrogen (N)	6.0%
Phosphate (P_2O_5)	4.2%
Grease, fat, etc. (by ether extraction)	7.3%

P. A.—The second claim of the patent you refer to is the strongest of the three, the first and third being limited to the exact form of the apparatus.

R. G. D.—Compounds of silver and vanadium can be used in place of platinum for the manufacture of sulphuric acid by the contact process.

P. A. B.—Full data as to Foreign Trade opportunities can be had at No. 315 Custom House, New York, or 629 Federal Bldg., Chicago, Ill.

B. S. B.—Small quantities of alum added to your water supply will remove the manganese compounds, and if you will forward a gallon sample, I will determine the proper quantity to use in your case.

R. F. D.—The cracking of reinforced concrete has been traced, in certain cases, to the use of brackish water or unwashed beach sand in its preparation. The bursting is caused by the formation of iron oxide on the imbedded metal.

Concrete is also destroyed by the formation of a voluminous, insoluble double compound of calcium aluminate and sulphate ($3CaO, Al_2O_3, 3CaSO_4$).

C. A. H.—The "Black Damp" in mines, which varies from 0.14% to 83%, is an accumulation of carbon dioxid and nitrogen present, in excess percentages, as found in pure atmospheric air.

A. S. T.—Storax, which is much used in the perfumery industry, is impoverished by the removal of cinnamic acid. The compounds of this acid give storax its peculiar odor. Some samples contain as little as 3% although the normal figure is about 30%.

E. A. W.—If you will send a pound sample of the material you mention, a complete chemical examination will be made of it, at a reasonable fee.

W. A. S.—Boiler compounds appearing on the market vary greatly in composition and should be examined and given a steam test before using in your boilers. A 4oz. sample is required for this test.

Charles B. Davis

Those whose inquiries to this department have not as yet received attention must bear in mind that unless replies by mail are specifically requested, communications can only be considered in the order of their receipt.—Editor.

DISTILLATES

News Notes of Chemical and Allied Industries

Oils and Minerals.

Great Western Oil & Chemical Company, Oklahoma City, Okla., has been incorporated with a capital of $2,000,000 to deal in oil and minerals of all kinds and to develop the same. The incorporators are R. H. Locke, A. J. McMahon, J. B. Dudley, all of Oklahoma.

Natural Oil and Gas.

The Great Eastern Oil & Gas Company, Aurora, Ind., has been incorporated with a capital of $100,000 to develop oil and gas lands and to market the product of the same. The incorporators are Louis Bloom, H. C. Williams, Aurora, Ind.; E. W. Crispin, J. M. Horless, Gulfport, Miss.; W. H. Bilerz, Belfar.

Chemicals, Dyes and Medicines.

Becker, Pennrich & Co., Inc., New York, has been incorporated with a capital of $20,000 to deal in chemicals, dyes, medicines. The incorporators are H. C. Becker, H. C. Pennrich, E. Brophy, 82 Beam street.

Fire Extinguishers and Chemicals.

American Fire Extinguisher Company, Pittsburgh, Pa., has been incorporated with a capital of $50,000 to manufacture chemicals, fire extinguishers of all kinds. The incorporators are W. A. McCoy, Pittsburgh, Pa.; W. I. N. Lofland, Geo. W. Morgan of Dover.

Window Glass Co.

McCoy Machine Glass Company, Huntington, W. Va., has been incorporated with a capital of $40,000 to deal in window glass. The incorporators are H. E. Camp, M. L. Camp, F. F. Rigall, P. P. Gibson and F. Mearns, Huntington, W. Va.

Edison in New Concern.

New Jersey Products Company, West Orange, N. J., has been incorporated with a capital of $500,000 to manufacture chemicals, glues, veneers, stains and shellac, paper products, phonographs, sound records and storage batteries, etc. The incorporators are Thomas A. Edison, Charles Edison, R. H. Allen, West Orange, N. J.; Stephen B. Mambert, East Orange, N. J., and A. C. Emery, Montclair, N. J.

Miscellaneous Chemicals.

William F. Eissing & Co., New York City, has been incorporated with a capital of $25,000 to deal in chemicals, liquids or solids. The incorporators are L. D. Della, D. F. Bodger, Morte S. Joseph, 299 Broadway.

Nitrogen Products Co.

The Nitrogen Products Company, Providence, R. I., has increased its capital from $200,000 to $500,000.

Glues, Gelatine, Etc.

United Chemical & Organic Products Company has been incorporated in Delaware with a capital of $2,202,700 to manufacture glues, gelatine, etc.

Westmoreland Co. to Improve Plant.

Plans have been filed by the Westmoreland Chemical and Color Company for alterations and improvements to its plant at Twenty-second and Westmoreland streets, Philadelphia, Pa.

Utica Co. Increases Capital.

The Utica Chemical Company, of Utica, N. Y., has increased its capital from $30,000 to $200,000 for expansion.

To Improve Phenol Plant.

The Butterworth-Judson Corporation, Newark, manufacturer of chemicals, etc., will make improvements to its phenol plant, which has been temporarily closed for this purpose.

New Charcoal and Chemical Plant.

Plans are being completed for the construction of a charcoal and chemical plant at Eastside, Oregon, by F. C. Harbaugh, Frank Kester and Fred Blaser. Alderwood and mill waste will be utilized in the inital plant.

Hoffman-LaRoche Increases Capital.

The Hoffman-LaRoche Chemical Works, 440 Washington street, New York, has increased its capital from $25,000 to $125,000 for expansion.

Chemicals.

The Wood-Percival Chemical Corporation, Richmond, Va., has filed articles of incorporation with capital of $300,000 to manufacture chemicals.

Parties to New Dye Merger Consider Further Plans.

At a recent meeting of the new National Aniline and Chemical Company, New York, it was decided to make the Schoellkopf Aniline and Chemical Works at Buffalo the assembling and shipping point for its finished products. The Benzol Products Company, which is also included in the recent consolidation, is erecting a large still-house at its plant at Marcus Hook, Pa., while work on the new buildings at the Beckers Aniline and Chemical Works in Brooklyn is progressing rapidly.

Capital Increase for Utica Co.

The Utica Chemical Company, Utica, N. Y., has increased its capital from $30,000 to $200,000 for expansion.

Colors and Chemicals.

The Peerless Color Company, Inc., Bridgewater Township, N. J., has been incorporated with a capital of $500,000 to manufacture colors and chemicals.

Dilworth Oil and Refining Co.

Dilworth Oil & Refining Company, Newkirk, Okla., has been incorporated with a capital of $1,000,000. The incorporators are J. R. Utterback and W. A. Doty, Newkirk; M. R. Diggs, Chicago.

Chemicals and Chemical Compounds.

The Colfab Manufacturing Company, Philadelphia, Pa., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical compounds. K. G. Bird, Philadelphia, is the principal incorporator.

Paper and Paper Stock.

Frederick G. Marquardt, Inc., New York, has been incorporated with a capital of $25,000 to manufacture paper, paper stock, etc.

J. L. Hoffman Co., Chemicals.

The J. L. Hoffman Company, Allentown, Pa., has been incorporated with a capital of $50,000 to manufacture chemicals. James L. Hoffman is president.

Aniline Dyes and Chemicals.

The Federal Aniline Corporation, New York, has been incorporated with a capital of $10,000 to manufacture and deal in dyes and chemicals. The incorporators are Richard Pick, Doris Lefkowitz, Arnold Blank.

Perfumes, Soaps, Etc.

Sardou, Inc., New York, has been incorporated with a capital of $25,000 to manufacture perfumes, soaps, toilet preparations. The incorporators are A. Keyrouse, B. C. Elliott, G. Sardou, 172 West 109th street.

Klipstein Increases Capital.

E. C. Klipstein & Sons Company, Chrome, N. J., manufacturer of chemicals and dyestuffs, has increased capital from $100,000 to $1,000,000 for expansion.

New Brooklyn Color Works.

Pioneer Color Works, Inc., Brooklyn, N. Y., has been incorporated with a capital of $10,000 to deal in colors and dyestuffs. The incorporators are A. C. Zobel, A. Galer, L. J. Schindler, 923 East Thirteenth street.

Ammonol Chemical Co.

The Ammonol Chemical Company, New York, has reduced its capital from $100,000 to $10,000.

Chemicals and Druggists' Supplies.

National Motor Power Company, Inc., Dover, Del., has been incorporated with a capital of $5,000,000 to manufacture chemicals and to deal in druggists' supplies of all kinds. Jas. Hughes, Mark W. Cole, Mary S. Pollock, all of Dover, Del., incorporators.

Dumas Appointed Georgia State Chemist.

W. C. Dumas, for eight years a member of the firm of A. M. Lloyd Laboratory, Atlanta, Ga., has been appointed State Chemist of Georgia.

Dr. Whitaker Heads U. S. Industrial Alcohol Co.

Announcement has been made of the recent election of Dr. M. C. Whitaker, head of the Department of Chemical Engineering, Columbia University, as president of the U. S. Industrial Alcohol Company. In assuming the duties of this office, Dr. Whitaker will also serve as chairman of the manufacturing committee in charge of plants and operations, chairman of the research committee in charge of the new laboratory at Baltimore, and as a member of the sales committee of the company.

Dr. Nichols to Head Sub-Committee on Chemicals.

Dr. William H. Nichols, of the General Chemical Company, New York, has been appointed by the Council of National Defence as chairman of a subcommittee of the committee on raw materials. The new committee will maintain offices in Washington, D. C. Other members of the committee are: Acids—E. R. Grasselli and Henry Howard. Fertilizers—Horace Bowker and Charles E. MacDowell. Alkalis—J. D. Pennock. Miscellaneous chemicals—Edward Mallinckrodt, Jr.

Prof. Zoller Investigates Possibilities of By-Products from Waste Grapefruit Culls.

In a paper read before the recent Kansas City meeting of the American Chemical Society, Professor Harper F. Zoller, of the Kansas State Agricultural College, described the results of his investigations on grapefruit with a view to utilizing the culls, which may not be shipped. His calculations show that in early winter the culls contain from 4.2 to 4.5 per cent citric acid, while the sugar content averaged 4.4 per cent. By late spring the acid content was reduced to 1.8 per cent, while the sugars rose to 8.5 per cent. Recoverable oil formed from 1.6 to 2.1 per cent of the peel, and a good yield of pectin was obtained from the skins. It was found that freshly picked early fruit is the most favorable for these by-products.

FOREIGN TRADE OPPORTUNITIES

These Opportunities for Foreign Business Relations Are Made Public by the Bureau of Foreign and Domestic Commerce, of the Department of Commerce, Washington, D. C. Names, Addresses and Details May Be Obtained from the Bureau or Any of Its Branches. Refer to the Number of Each Opportunity and Place Inquiries for More Than One on Separate Sheets.

Dyes; Perfumes.

23938.—A man in Russia wishes to be placed in communication with American manufacturers and exporters of dyes, boots and shoes, cloth, hardware, machinery, and perfumes. Catalogues, samples, and full information should be submitted.

Medical Picture Slides.

23959.—A doctor in Canada desires to purchase picture slides suitable to accompany illustrated lectures by physicians on public-health subjects, especially on subjects illustrating blood circulation. Quotations should be made f. o. b. New York, Boston, or other eastern city. Payment will be made by cash. Correspondence may be in English.

Lime and Portland Cement.

24110—A firm in Argentina is in the market for three grades of white lime in 220-pound casks and Portland cement in 396-pound barrels, gross weight. Quotations should be made c. i. f. destination. Payment will be made against shipping documents upon receipt of goods. Correspondence should be in Spanish. References.

Potato Starch; Copper Sulphate.

24094—A firm in the United States reports that its agent in Spain is in the market for 3,000 tons (2,204 pounds each) of sulphate of copper for delivery in April, and 2,000 tons for delivery in March and May; 10 to 500 tons of potato starch; sheet tin for packing sweets, covering champagne bottles, and for paper-plated sheets. Samples of the potato fecula should be submitted. Quotations should be made f. o. b. New York.

Drugs and Chemicals.

24096—A firm in Spain desires to secure an agency for the sale of chemicals and drugs, such as aspirin, antipirine, benzoic acid, acetone, aniline colors, aniline arseniate, betel leaves, benzonaphthol, benzoates, bromide of potassium, pure bromide, chloroform, carbonate of guaiacol, cocaine, hydrochlorate and muriate, fluoric acid, heliotropine, camphor oil, mercurial preparations, naphthol, menthol, opium, iodine, iodate of potash, oxide of bismuth, iodoform, ipecac, urate, etc. Quotations should be made c. i. f. destination. References.

Chemicals.

24134.—A commission merchant in Colombia desires to be placed in communication with American manufacturers and exporters of hardware, dry goods, chemicals, drugs, notions, etc., and particularly wheat. A complete list of the articles desired may be obtained from the Bureau or its district offices. References.

Chemical Fertilizers and Chemical Products.

24222.—A man in Spain desires to secure an agency for the sale of chemical fertilizers and other chemical products used in agriculture. Correspondence should be in French or Spanish. References.

Phosphorescent Preparations.

24229.—A firm in Spain wishes to buy phosphorescent preparations other than for dial purposes. Payment will be against shipping documents or by cash. Correspondence should be in Spanish. References.

Chemicals.

24130.—A firm in Spain wishes to secure an agency for the sale of bichromate of soda, bichromate of potash, aniline oil, sulphate of aluminum, alum, and sulphate of copper. Quotations should be made c. i. f. destination. Correspondence should be in Spanish or French. References.

Sugar Substitutes.

24203.—A firm in England is in the market for sugar substitutes, dried milk, and dried or liquid eggs. Quotations should be made c. i. f., if possible. Payment will be made by cash against documents in New York.

Drugs and Chemicals.

With capital stock of $100,000, the H. A. Metz Laboratories, Inc., drugs, chemicals, etc., has been incorporated under the laws of New York by C. Fuehrlein and G. P. and H. A. Metz.

Aniline Colors and Chemical Products.

24245.—A commission merchant in Spain desires to secure an agency for the sale of aniline colors and chemical products. If possible, quotations should be made c. i. f. destination, otherwise, f. o. b. New York. Payment will be made against shipping documents through a local bank. Correspondence may be in English. References.

Acetate of Lime.

24045—A mining engineer in Argentina is in the market for acetate of lime. Quotations should be made f. o. b. American port, per ton or minimum number of tons. He also desires to receive catalogues and terms from American manufacturers and exporters of machinery for making acetic acid. Payment will be made by cash against documents of one-half cash with order and balance against documents. Correspondence may be in English. References.

Chemical Products; Dyestuffs.

24447—An exclusive agency is desired by a commission merchant in Spain for the sale of chemical products of all kinds and dyestuffs for silk, wool, and cotton textiles, or authorization to register purchased goods with his own trade mark. Quotations should be made c. i. f. destination. Payment will be made against delivery of shipping documents. Correspondence should be in Spanish. References.

Colors and Dyestuffs.

24422—A firm in India desires to represent American manufacturers and exporters of colors and dyestuffs.

Chemical Products.

24418—An agency is desired by a man in Brazil for the sale of chemical products, drugs, pharmaceutical products, etc. Quotations should be made c. i. f. destination. Correspondence may be in English. References.

Chemical Products.

24333—A man in France desires to secure an agency for the sale of all kinds of chemical products. Quotations should be made c. i. f. French port. Correspondence may be in English. References.

Chemical Products and Chemicals.

24369—A man in Italy wishes to secure agencies for the sale of chemical products, drugs, pharmaceutical products, paraffin wax, caustic soda, carbonate of soda, vaseline, bronze and aluminum powder, lampblack, raw matetrials for making varnish, lard oil, wood oil, white spirit, and lithopone. Quotations may be made c. i. f. Genoa. Correspondence may be in English. References.

Celluloid in Sheets.

24434—A firm in England wishes to purchase 1,000 sheets of celluloid for making Christmas cards. Samples of the celluloid desired may be examined at the Bureau or its District Offices. (Refer to file No. 84805.) Quotations should be made c. i. f. destination. Payment will be made by cash against shipping documents at destination. The celluloid should be packed in wooden cases. Reference.

Fertilizers.

24064—A firm in Spain wishes to secure an agency for the sale of all kinds of fertilizers. Quotations should be made c. i. f. Spanish port. Correspondence may be in English. References.

Colors and Chemicals.

24410—An agency is desired by a firm in India for the sale of colors, such as methyl violet, methyl blue, logwood extract, etc., and chemicals of all kinds, such as alum, sulphates, sodas, rosin, quicksilver, glycerin, etc. Quotations should be made c. i. f. or f. o. b. destination and Karachi. Payment will be made by 60-day sight draft through a New York firm. Correspondence may be in English. References.

Algarrobilla for Tanning.

24432—A company in the United States acting as purchasing agents for firms in Japan is in the market for positive and negative moving-picture films, lathes, held wire for spinning mills, algarrobilla for tanning, and "motaragaut" gum. Reference.

Colors and Varnishes.

24262—A commission merchant in Spain desires to purchase and secure exclusive agency rights for the sale of water soluble blue ultramarine, and all kinds of colors and varnishes. Quotations should be made c. i. f. destination. Payment will be made against shipping documents at destination. Correspondence should be in Spanish. Reference.

Chemicals for Soap, Shoe Polish, and Tanning.

24269—A firm in the Canary Islands is in the market for machinery and chemicals used in the leather-tanning industry and chemicals used in making soap and shoe polish. Quotations should be made f. o. b. New York. Cash will be paid. Correspondence should be in Spanish. Prices and full information should be submitted.

Petroleum.

24259—A foreign purchasing commission in the United States desires to place orders for large quantities of petroleum, such as is used by the United States Navy.

Chemicals for Aerated Water.

24406—A company in Peru wishes to purchase clear green, transparent, 4 and 8 ounce glass bottles, with glass ball stoppers, for aerated waters, and chemicals used in the manufacture of aerated water, such as bicarbonate of soda, citric acid, sulphuric acid, tartaric acid, etc. Payment will be made by cash against documents through a local bank. Quotations should be made f. o. b. New York or San Francisco. The bottles should be packed in crates or barrels of 1 gross each. Correspondence may be in English. References.

Foreword

THE evolution of American technical chemistry has been characterized hitherto by a deplorable lack of symmetry, of coordination, of even and harmonious development. No country upon the face of the globe possesses in equal variety, and such vast quantity, the raw materials required in industrial chemistry. In no other country is the domestic demand so great. In certain fields American chemical talent and enterprise have shown marvelous powers of expansion and the ability to completely dominate the domestic situation, and even enter aggressively foreign markets. Notable examples are our metallurgical industries, the fertilizer industry, sulfur and sulfuric acid, electro-chemistry, the soda industry, the oils and fats, etc., etc.

In other fields there has existed for years an almost complete dependence upon chemical products of foreign origin. With folded arms we have watched the chemists of a few European lands manufacture a variety of wares—often from raw materials furnished by American forest, field or mine—and send them broadcast to the markets of the world. Among others, they have supplied the current needs of thousands of American industrial plants, requiring, in varying amounts, a large number of diverse chemicals.

Our economic fabric, our existing chemical industry, our inventors, our schools of science and technology, all connected directly or indirectly with applied chemistry, have suffered from this lack of a harmonious development of industrial chemistry upon American soil.

That admirable unity, symmetry and many-sidedness—or rather all-sidedness—which characterizes marvelously the German chemical industry, and constitutes the chief source of its power, has, during the past, been conspicuous by its absence in this country.

In no branch of chemical technology have we been so distressingly behind the age as in the manufacture of coal-tar compounds. The industry, with its multitudinous ramifications, seemed firmly established and buttressed in Germany. Its dominance of the world's markets was such that, with the exception of little Switzerland, no competing industry worthy of the name was able to maintain an existence in other lands. In England and France the struggle towards emancipation was more marked. In the United States there was little more than the semblance of a coal-tar chemical industry.

The abnormal conditions attendant upon the titanic struggle raging across the Atlantic have furnished to the lands hitherto dependent upon German chemicals an intense stimulus to found their own domestic coal-tar chemical industries, and, at the same time, have ensured the most favorable possible environment for the establishment, upon a permanent basis, of all the various phases of this, the most complicated of the globe's different branches of technical activity.

This movement has found its most complete expression in our own country. With a degree of rapidity never before witnessed in so short a period, an American coal-tar chemical industry has been founded, and is daily extending the amount of its output, the scope of its activity and the variety of its products.

We can practically fix the date when we shall manufacture in American works, from American coal tar, the great bulk of the more staple colors, medicinals, photographic chemicals, etc., which prior to 1915 came almost exclusively from German factories. We can even confidently look forward to a period, in the very early future, when we shall produce the host of minor modifications, required in small quantities, but still constituent parts of a self-contained industry, with the enrollment of which among genuine American products, our complete independence in this field shall be achieved.

Such an industry, of nation-wide extent, a magnificent national asset, offering a multitude of openings for American ingenuity, enterprise, inventive talent and scientific attainments, bound to make itself soon felt in our foreign export trade, furnishing indispensable materials for several million workmen in our textile and allied branches, has a legitimate right to possess its own organ.

Our fertilizer chemists, our rubber chemists, our leather chemists, those in electro-chemical, metallurgical, illuminating and similar industries, have their special organs.

It has quickly been recognized that those identified with coal-tar chemistry, as manufacturers of all its varied products, as dealers or as consumers, as supplying the mechanical accessories for the industry, should have at their service a publication devoted primarily to their combined interests.

The publishers of the CHEMICAL ENGINEER, after consultation with representatives of the various interests involved, have decided to devote the periodical chiefly to these varied interests. Its columns will be open to the free discussion of the many problems, technical, economic and fiscal, connected with the steady, healthful evolution of the industry, and the most advantageous and profitable uses of its products.

The division of synthetic colors will necessarily occupy the most space. In this connection, on account of the close relationship, full consideration will be devoted to the manufacture and utilization of natural dyes.

The ideal of the editorial management will be to offer a medium for the prompt and full publication of all progress made by American chemists in developing the manufacture and application of synthetic colors and other compounds derived from coal tar, and to place at their service exhaustive and complete résumés of all advances chronicled in other lands.

Ample assistance in this effort will be rendered by a Board of Associate Editors, representing effectively the various categories of interests enumerated.

No pains will be spared to render this new phase of the CHEMICAL ENGINEER'S activity thoroughly equal, and, if possible, distinctly superior, in point of variety, fullness, accuracy, illustrative features and collective exhibits of samples, to any of the European periodicals devoted to special divisions of its more comprehensive field.

THOMAS H. NORTON.

THE MERGER OF LEADING AMERICAN MANUFACTURERS OF COAL-TAR CRUDES, INTERMEDIATES AND COLORS

IN April of this year general interest was aroused by the announcement of the prospective merger of several of the leading factors in the American coal-tar chemical industry.

The details of this merger have been perfected since then. At the beginning of June the "National Aniline and Chemical Company" of West Nyack, N. Y., with a capital of $17,231,000, was incorporated by I. Frank Stone, William N. McIlravy and William Beckers.

The three leading constituents in this combination are the Schoellkopf Aniline & Chemical Works of Buffalo, the W. Beckers Aniline & Chemical Works of Brooklyn and the Benzol Products Company, having its main works at Marcus Hook, Pa. Another integral factor is the National Aniline & Chemical Company of New York, which has been the selling agency of the products of the Schoellkopf Aniline & Chemical Works of Buffalo. It has, however, conducted a large and successful trade in staple chemicals, and in this connection maintained a small factory on Long Island.

Furthermore the new organization includes certain interests and manufacturing features of three other powerful companies, the Barrett Co., the General Chemical Co. and the Semet Solvay Co. These constituent parts of the merger deserve individual description and analysis.

The Schoellkopf Aniline & Chemical Works is the oldest and most powerful of existing American producers of artificial colors. It was founded in 1879 at Buffalo. Amidst much of discouragement, struggling for years against unfavorable economic conditions it has endeavored in every possible way to build up a genuine American coal-tar color industry. Several synthetic dyes, of recognized value in the world's markets, were invented and first produced in its works. At the outbreak of the current war the company was manufacturing some 106 different artificial dyes, in varying amounts. Practically all of these products were made from intermediates of European origin. After 1914 the company was forced to depend largely upon intermediates of its own manufacture, supplemented, however, by aniline of American make. The variety of dyes produced was immediately cut down to less than a score. The list included staple colors of large consumption, most easily and rapidly manufactured.

Attention was devoted chiefly to the production, on a vast scale, of the black dyes, constituting about three-quarters of our normal consumption. During the past two years the variety of colors has again expanded. A large amount of capital has been invested, and the erection of new buildings with their subsequent mechanical equipment, has been upon the most generous scale. It is undoubtedly owing in great part to the unwearied and farsighted plans and efforts of this company that the pinch of our "dyestuff famine," at the close of 1915, was not felt more severely. Today it represents the largest aggregate of capital, experience and output in the domestic industry. It is, logically, the nucleus around which other factors in the industry would naturally crystallize.

The W. Beckers Aniline & Chemical Works, of Brooklyn, is of quite recent origin. Dr. Beckers, a graduate of the University of Heidelberg, and with broad experience in color chemistry, founded a modest factory in 1912, in which some 15 synthetic dyes were regularly produced prior to the war. He quickly grasped the possibilities of the situation early in 1915. Capital was enlisted, and a large, well-equipped color plant was swiftly erected. Today the buildings number about 40, the capital is $5,000,000 (about one-half of the presumed capitalization of the Schoellkopf company) ,and where one workman was employed in 1914, now 100 are busied. The Beckers works specialize on colors for wool, while cotton dyes predominate in the output of the Schoellkopf works.

Shortly before steps were taken to consummate the merger in question, the Beckers Aniline & Chemical Works notably increased the range of its operations by acquiring the Standard Aniline Products Co. This latter was organized in New York early in 1915. Its works at Wappinger's Falls and at Newburgh have attained considerable proportions. The output consisted at the beginning mainly of b-naphthol and p-nitraniline. Sulphur black and a few other staple colors were successively added, until the company finally became a factor of some importance in the dyestuff situation.

The Benzol Products Company came into existence late in 1910. It was organized by representatives of the Barrett Co., of the Semet Solvay Co., and of the General Chemical Co. These several companies felt that the time was ripe for establishing in this country the manufacture of aniline and possibly other coal-tar intermediates. The Barrett Co., which has done so much to build up an American coal-tar industry, was, then, the chief producer of benzene and other coal-tar crudes, in varying degrees of purity, derived from its numerous tar works. The Semet Solvay Co., actively engaged in the construction of coke ovens, and occasionally of benzol recovery plants, controlled, likewise, a certain supply of benzene, toluene and xylene, secured from the scrubbers of these plants. Finally the General Chemical Co. was in a position to supply the acids and other chemicals needed in the manufacture of aniline and allied compounds at an extremely low cost. It was felt, and quite correctly under existing conditions, that by a union of the interests, eliminating all unnecessary costs, American-made aniline was a practical proposition. And so it was. Bitter competition, however, on the part of European rivals, soon made its appearance. The price of aniline, in this country, descended rapidly. In 1914 the Benzol Products Co. was struggling to keep up its manufacture, with current rates below its cost of production. The war put an end to this attempt to throttle the young industry. The organization promptly recognized the possibilities before it. The plant has been multiplied many fold, and the company is now furnishing, in great amounts, a variety of the leading intermediates needed by the growing color industry.

The same reasoning, which lay at the basis of the foundation of the Benzol Products Co., in drawing together mutually interested factors, each capable of contributing an essential part, has lead to the vastly greater merger of the three constituents, enumerated above, in the National Aniline & Chemical Co.

The three parent organizations of the Benzol Products Co. are in a position to contribute, with equal advantage, to the new, comprehensive corporation. The Barrett Co. has multiplied its facilities for producing on the most ample scale, in a high state of purity, all the crudes required in the industry.

The Semet Solvay Co. has likewise multiplied its plants for furnishing the hydrocarbons coming within its purview. It has, in addition, embarked most successfully upon the manufacture of two important coal-tar derivatives, salicylic acid and sulphur black.

The General Chemical Co. can provide, with ease, all the many chemicals required in a comprehensive, self-contained color industry.

The newly formed organization is, therefore, distinctly in advance of the individual, large dyestuff plants of Germany. A very few, such as the famous "Badische" company, manufacture some of the leading chemicals needed and more or less of the intermediates employed.

None, as far as the writer is aware, control sources of crudes, or such a general supply of intermediates and of ancillary chemicals, as will be the case in the new American organization.

To all connected with our young coal-tar chemical industry, either as producers or consumers, and to not a few outside, this important consolidation gives rise to some most interesting questions of a combined economic, ethical, legal and patriotic nature.

Among them are the following:

Will this move towards consolidation progress, and to what extent?

Is it desirable in the interests of American consumers of artificial colors?

Will it aid or retard the evolution of a comprehensive, self-contained American color industry?

What will be the effect on our ability, under normal conditions, to meet foreign competition in the international markets for coal-tar products?

As far as the general desirability of consolidation is concerned, the writer is firmly convinced of the wisdom of the policy, and cannot do better than reproduce an expression of opinion, contained in an address before the New York Section of the Society of Chemical Industry, on October 22, 1915:

"There are several other phases in the evolution of an American color industry which deserve careful attention at the present time.

"The first is connected with the somewhat rapid entrance into this field of a number of separate interests, imperfectly acquainted with the complexity of the problem.

"It is well known to every one who has studied the fundamental basis of the past dominance of German color chemistry in the world's markets, that the chief cause of this marvelous control lies in the solidarity of the German industry as a whole. It is so organized that all the correlated parts act in unison. They form practically a unit when, in any land, a serious effort is exerted to secure freedom from dependence upon foreign sources of color.

"The question now arises, Is it not eminently desirable that a comprehensive American coal-tar industry, striving to supply nearly all American tinctorial needs, with products made from American raw materials, should possess a higher degree of unity—financial, technical, commercial—than now is the case? Is it not of prime importance that all unnecessary overlapping and duplicating of effort be excluded, at least in the formative stage?

"The problem is more easily stated than solved. It is economically important, during the initial period, that the industry should be characterized by that unity and solidarity which contribute so largely to the might and effectiveness of the German rival; and yet it must be free from any tendency toward monopolistic power.

"For the moment it suffices to express an aspiration, a hope, for economic conditions which may powerfully aid a young industry in bravely holding its own."

Since the date, abovementioned, the power and strength of the German coal-tar chemical industry has been mightily heightened. The leading factors, acting ordinarily in unison upon matters concerning the export trade, entered, a year ago, into a formal organization with a high capitalization, for the distinct purpose of winning back, and holding the markets of foreign lands, where determined efforts were being made to create domestic color industries. This move was actuated largely by the rapidity with which capital and enterprise were building up an American rival.

The aims of this organization are to bring about the closest correlation between all phases of the coal-tar chemical industry, so as to eliminate every unnecessary item of cost, as soon as the old-time activity is resumed; and, furthermore, to conduct most energetic and determined campaigns in countries, such as the United States, in order to recover the former supremacy.

This attitude on the part of the giant rival across the Atlantic might have caused more serious apprehension among those connected with the upbuilding of the young American industry, familiar, as some of them are, from personal experience, with the weapons likely to be employed, were it not for the statutory provisions against unfair competition, on the part of foreign manufacturers and importers, contained in the Federal enactments of September 8, 1916.

Even with the danger of deliberate, prolonged underselling, below the cost of production, eliminated from prospective commercial warfare, there is not the slightest question but that our American manufacturers of synthetic colors will be put upon their mettle when the day arrives for the great factories on the Rhine and the Spree to ship their products freely to this side of the Atlantic.

There will be a powerful combination of lengthy experience in salesmanship, of friendly relations with consumers, of well-equipped laboratories, of offerings of colors not yet produced in American works, as an inducement to exclusive trade, and all the other devices at the service of a long-established import trade. The protection of a fairly adequate, although unevenly constructed, tariff may not suffice to ensure a successful outcome in the contest.

The American industry must resort to the same class of weapons as those employed by the European rival. Of these the chief one is *consolidation*.

It does not necessarily imply a disappearance of name and individuality on the part of constituent members. There is no plan for this in the big American merger under consideration. It does, however, mean the complete cessation of all duplication of effort, scientific, technical and commercial. A single selling organization suffices for the entire series of productive factors. Free consultation between the respective chemical staffs will prevent overlapping in plans or in production, and will lead to a healthful cooperation, whereby each can profit from the criticism and suggestions of professional colleagues.

The result will be that costs of production can be steadily lowered, that standards of purity and uniformity can be continually raised, that the varying needs of the thousands of consumers of tinctorial wares can be met more easily, adequately and satisfactorily.

There will be the *élan* and *esprit* of an army, well-officered, under capable leadership, rather than the guerrilla warfare of scattered bands.

Viewed in this light there can be little doubt that the consolidation of our coal-tar chemical interests on an intelligent, generous, patriotic basis, provides the most effective defense against the possibilities of bitter, even vindictive onslaughts by foreign rivals at no remote date; and, furthermore, that it furnishes our strongest insurance for an economical, well-balanced evolution of the domestic industry. It will mean perfect coordination and correlation at every stage of the growth; avoiding loss of by-products, meeting first the heavy demands for a comparatively small number of staple colors; then adding steadily the dyes consumed in limited amounts, but of great utility in numerous minor phases of industrial activity; finally dovetailing in all the coal-tar products of non-tinctorial value, medicinals, perfumes, developers, etc., until the American industry is complete in every sense of the word.

Logically and actually this ideal can be attained only by a combination of all existing factors. It is not known whether those included in the present merger plan to invite further additions to their number, or whether their attitude will be the reverse.

The facts in the case would all point to the wisdom of a course characterized by generosity and helpfulness, towards scores of minor enterprises in the broad field, and of cordial cooperation with a few more powerful factors. It would be the patriotic and genuinely American attitude to assume—in harmony with that deep current of feeling sweeping through the nation, as we send our youth in arms, and our loans of billions across the ocean.

A vast amount of the nation's capital has been invested in scores and scores of plants, scattered over our country, engaged now in the production of coal-tar intermediates and dyes. A multitude of men are gaining experience in all the various phases of the industry. An elastic policy of consolidation, affiliation or cooperation with these diverse units of a big national asset, on the part of an overshadowing, and to a certain extent, dominant factor, would have a broad economic bearing. It would insure a continued and profitable utilization of men, capital and plant.

As an industry becomes more and more perfected in methods and mechanism, centralization is inexorably the rule. Some years must inevitably pass before the tendency may be felt very strongly. In the meantime it would be of most pronounced value to the separate units, to the industry as a whole, and to the nation, if most existing elements could be brought into direct cooperation with the newly constituted organism.

Such unity and solidarity would be of incalculable value, as the industry expands and one color after another will be produced in amounts more than sufficient to meet domestic demands. If we sally forth into the world's markets we must meet the close competition of German wares, not only in quality but in price. If we are to succeed, the cost of production must be brought to the lowest possible point. Nothing will further the attainment of this end better than to retain in the industry every keen-witted enterprising man who has been enlisted during the emergency call of the past two years.

We have no surplus of experienced coal-tar chemists and coal-tar operatives to draw upon, as was the case in Germany—prior to the great war. We are slowly training the men who will be the brains for us scientifically and technically when we enter upon the struggle for foreign markets. Hence, let us carefully retain in the industry every human asset.

An artificial color represents the combined result of an enormous amount of most varied inventive and constructive ability. It falls into the same category as a watch, a typewriter, a machine tool, a locomotive. We can confidently look forward to an early date when our American color industry, thoroughly standardized, and perfected in every detail, will win a place in international trade, quite as secure as that of any of the articles cited, and scores in addition. But to accomplish this we must not neglect a single one of the many factors involved.

It may be urged that in the above considerations, not the slightest attention is paid to the laws of competition, and to the desirability of affording them free play in the evolution of the new industry. In reply it may be said that some time must elapse before a national, well-rounded coal-tar chemical industry can physically be evolved. During this period the absence of competition is the most desirable feature. It is owing to the fact that German competition is non-existent that the industry has gained its start. Under normal conditions, facing German competition of the keenest nature, modified by the restrictions of a tariff, destined more and more to reflect purely demonstrable differences in cost of production, the American consumer of dyes can rest assured that his legitimate interests will be protected, no matter whether there is a single, collective American organization for the production of synthetic colors, or a battalion of small units.

Dr. B. C. Hesse has aptly termed the coal-tar dyestuff industry "a one-nation industry," and raised the pertinent inquiry, whether on purely economic grounds it might not be better to leave the creators of the magnificently equipped and organized German color industry to the quiet enjoyment of well-earned rewards. There is much to be said on both sides of such a question. As a matter of fact, however, we finally have our American industry deep-rooted and bound soon to reach the point where it will fairly well meet the nation's tinctorial needs.

The question may here also be pertinently asked, whether it would not be economically advantageous for this country if a single, well-organized combination of existing and prospective factors controlled its coal-tar chemical interests. The proposition is warranted by the marvelous complexity of the industry, beyond that of any other phase of human activity, requiring logically the closest coordination between all of its multitudinous ramifications.

With the assurance of scientifically adjusted tariff rates, and the consequent check of watchful foreign competition there is much to lead to the conclusion that the principles upon which the recent merger is based, and the extension of its organization so as to include the remaining factors in the branch, will inure in the highest degree to the early and successful establishment of a comprehensive, self-contained American coal-tar chemical industry.

AMERICA'S CHEMICAL PROGRESS

By George H. Bruce, A.M., LL.B.

AND then, "The United States came into her own!" Nor will we find it necessary to await the cessation of the world's hostilities to make that a truism.

Overnight, almost, our industries seemed to be on the verge of chemical starvation. Manufacturing interests that required generations to build and millions to maintain, found that they had placidly drifted along, ordering and using foreign colors and chemicals, turning a deaf ear to the occasional venturesome individual who defied tradition and staked his all to offer something "Made in U. S. A.," that would answer the purpose of the foreign goods.

It would seem impossible to conceive a more hopeless, a more unprofitable, a more discouranging task, to undertake in the United States, prior to August, 1914, than to enter into the dye and chemical business. Not that we did not have some large plants that were successful; but considering that the field was a country of one hundred million people, and that industries involving millions and millions of dollars depended on foreign made goods for the greater part, our contribution was negligible.

The American is nothing if not a good philosopher. You can picture him saying in his matter-of-fact way, "Well, they must have goods and we must make them." So he proceeded to enter a field of industry that called for scientific knowledge, for vast capital, for much experiment and consequent waste, with the same nonchalance that he displays when he bores on the market, learns to dance, rides a horse or plays golf. "If it must be done, why worry over it and make the task so much more arduous?" Then the color and chemical works sprang up all over the country. Great coke plants began to recover the valuable benzol that had been used as fuel or wasted. And the chemists proceeded with their work of constructive independence. The libraries were filled. Chemical and industrial works of reference were in constant use. Gradually products were turned out. A few at first, but, Oh, Ye Gods! What some of those products were! "Nothing like them were ever before seen upon the earth, and in the heavens above the earth, nor in the waters under the earth!" We prayed and worked and pleaded, encouraged and scolded, but never a falter nor a surrender, and while all perhaps [illegible] and proceeded to one failure followed another and another experiment was sent down the sewer, and always was there a helping hand and a more experienced workman to straighten out kinks. Back of it all stood the departments of our Federal Government, especially the Bureau of Foreign and Domestic Commerce, with its talented, self-sacricing staff, co-operating and working with such zeal, such patience, such ability, that slowly but surely the infant industry grew to man's size, with a capital of many millions. Nor is that the most encouraging feature, but rather, that from nothing, and then chaos, have arisen solid, substantial industries, systematized as well in their business methods as in their products. The art of standardization has been acquired, waste is replaced by useful by-products; and—wonder of wonders!—consumers are not only buying domestic products willingly, but are actually converted.

It is within the writer's knowledge that some large consumers have refused the offer of foreign goods of the highest standard, and given out contracts for domestic wares, not, as they confess, out of patriotism, but solely because they found them better. Confessedly the most sanguine never dreamed of such a condition prevailing in less than three years. True, there is much yet to do, oh, so much; but as we view conditions in the retrospect we need have no fear for the future.

To those not "of the cloth," as it were, it is impossible to realize the little less than miracles that have been accomplished. Yes, they have produced the so-called impossible colors; they have even gone the foreign genius one better and proceeded to extract colors from autumn leaves and produce a commercially valuable dye.

Yes, it looked like a Herculean task which we had on hand; but, perhaps, like no other people, the American rises to an occasion. Whether it is to build a canal theretofore called impossible, an air ship that will fly or a color that apparently only a foreigner could make, he finds a way of "getting there" that is truly refreshing and delightful. All the time, while "getting there," he is standing your abuse, ridicule and scolding—much of which he deserves—without a word of complaint, because he knows he deserves it. But does that discourage him? Not much! He grits his teeth and says, "I will show them!" And he does. HE HAS! My hat is off to the American. This is, briefly, the progress of the chemical and color industries in the United States of America, and the future has even greater wonders to unfold.

COAL-TAR CHEMISTS TO ADVISE GOVERNMENT.

The Chemical Committee representing all phases of the chemical industry which has been organized for consultation and cooperation with the Council of National Defense and the Advisory Commission to dispose of all problems connected with the supply, conservation, distribution and production of chemicals and their combinations, includes the following names in the sub-committee on coal tar by-products and the synthetic phenol division:

Coal Tar By-Products.

William Hamlin Childs, chairman, The Barrett Company, 17 Battery Place, New York; J. A. Toppin, Republic Iron and Steel Company, New York City; H. H. S. Handy, Semet-Solvay Company, Syracuse, N. Y.; C. J. Ramsburg, H. Koppers Company, Pittsburgh, Pa.; W. H. Gartley, United Gas Improvement Company, Philadelphia, Pa.; W. A. Addies, Consolidated Gas Company, New York City, and Captain W. E. McKay, New England Coke and Gas Company, Boston, Mass.

Synthetic Phenol Division.

H. H. Dow, Dow Chemical Company, Midland, Mich.; W. A. Bradford, Butterworth-Judson Company, New York, N. Y., and Captain McKay.

II

COAL-TAR CRUDES

STANDARDIZATION OF BENZOL TESTS IN COKE WORKS

IN British coke plants there is a wide diversity among the methods employed to test the efficiency of the benzol scrubbers. The Miller test, so largly used in Germany, is chiefly in vogue.

T. B. Smith, in a recent address before the Coke Oven Managers' Association, at Darlington, recommended strongly the following mechanical method: Creosote oil is used as an absorbent in preference to oleic acid, or nitrobenzene. The fraction boiling between 240° and 270° is thoroughly washed with acid and soda in order to remove tar acids, pyridine bases, etc. It is then allowed to stand upon ice until the naphthalene present is frozen out. This purified absorbent is introduced into a series of four bottles of 100 c.c. capacity, and of a type offering a maximum surface of contact.

The gas to be tested, after passing through drying towers, is conducted through the absorption train—each bottle being surrounded by ice—to the meter at the rate of 8 to 10 liters per hour. After 100 liters have passed the apparatus is disconnected, and the absorbent is distilled until 50 c.c. are collected, this, in turn, is redistilled, and the distillate, up to 160°, is collected and measured. A parallel experiment is made with 50 c.c. of the crude benzol of the day's run, and the quantity distilling to 160° is measured. These results furnish the data for a simple calculation. For example, if the absorbent yielded 3 c.c. of distillate passing below 160°, and 50 c.c. of the crude benzol of the day's run yielded 37.5 c.c. up to the same temperature, then the 100 liters of gas passing through the absorbent must have surrendered 4 c.c. of crude benzol.

This short and easy method gives results in close accord with those obtained by the more lengthy Müller test.

An almost as accurate chemical method employed by Smith is the following: 100 liters of coke-oven gas are passed through an acid absorption system at the rate of 10 liters per hour. The apparatus consists of 4 bottles and a final U-tube containing calcium chloride. In bottles Nos. 1 and 2 is a mixture of nitric and sulphuric acids in the proportions of 70 per cent. sulphuric to 30 per cent. nitric. No. 3 contains distilled water, and No. 4 approximately twice-normal NaOH solution.

All aromatic hydrocarbons passing through the apparatus are nitrated, the products collecting in a supernatant layer, floating at the top of the acid in bottle No. 1. The nitric fumes evolved are all absorbed in bottles Nos. 2 and 3. The gain in weight of the entire absorption apparatus gives the quantity of aromatic hydrocarbons in 100 liters of gas.

Monthly tests of the amount of gas evolved with carbonization of a ton of coal are advised. Many chemists base their calculations on the general statement that a long ton of coal yields 10,000 cu. ft. of gas. There are, however, in practice, wide divergencies from this figure, depending upon the class of coal used, and notably upon the temperature of carbonization.

In these days, when the demand for benzene, and especially for toluene, is so urgent, it is found desirable to neglect no precaution in insuring a maximum recovery of the hydrocarbons present in coke-oven gas.

Receivers of Aetna Explosives Co. Secure Privilege to Fulfil Contract.

The receivers of the Aetna Explosives Company have been authorized by the courts to enter into a contract with the Pittsburgh By-Product Coke Company for the purchase of a quantity of toluene at $1.35 per gallon, solvent naphtha at 13 cents per gallon, and benzene at 45 cents per gallon. The purpose of granting this privilege was to enable the receivers to deliver to the French Government 1,000,000 pounds of "T. N. T." per month, as per contract.

Explosion in Barrett Co. Plant.

A recent explosion in the naphthalene building of the Barrett Manufacturing Company's chemical plant Frankford, Pa., completely destroyed the building and started a conflagration which burned portions of several others, causing a total loss of $40,000. Officials of the company say that the fire was caused by a tank overflowing and the contents coming in contact with a stove. It was believed that operations could be resumed within a few days.

Lines of Advance in Coking Practice.

In an address before the Yorkshire section of the Society of Chemical Industry, G. E. Foxwell advocated earnestly the desirability of shortening the carbonizing period in order to increase the output. He advises the recovery of benzol of much lower strength than is now the rule, the product to be washed for phenol. He claims that by aiming at a benzol of 55 per cent., instead of 65 per cent, as at present, there is a marked increase in the amount of toluene recovered.

Mr. Foxwell urges strongly the establishment, at coking centers, of the necessary plants for refining the hydrocarbons, and for producing from them many of the simple intermediates, such as aniline, the toluidines, etc.

It is worthy of note, in this connection, that such a policy has already been adopted by several American coking companies.

The American Tar Product Company will erect at Woodward, Ala., an addition for the manufacture of naphthalene.

III

COAL-TAR INTERMEDIATES

A CYCLIC PROCESS FOR THE MANUFACTURE OF PHENOLS

Professor Louis M. Dennis, of Cornell University, has recently (Amer. Pat. 1,227,894, of May 29, 1917), devised a cyclic method for the manufacture of phenols from aromatic hydrocarbons, which claims distinct economic advantages over current processes.

The following is a description of the sequence of operations for transforming benzene into phenol. It is naturally, applicable to the production of a large number of the hydroxyl derivatives of aromatic hydrocarbons:

"Benzene is treated with sulfuric acid, preferably fuming sulfuric acid, to produce benzene-sulfonic acid in excess of sulfuric acid. This mixture is treated with benzene. As the sulfuric acid is practically insoluble in benzene, the latter takes up the benzene-sulfonic acid, but not sulfuric acid to any appreciable extent, forming a benzene solution of benzene-sulfonic acid, substantially free from sulfuric acid. This benzene solution of benzene-sulfonic acid is treated with water, which dissolves out the benzene-sulfonic acid and separates the same from the benzene.

"In order to initiate the process and to produce the initial charge of sodium benzene sulfonate, the aqueous solution of benzene-sulfonic acid, substantially free from sulfuric acid is treated with an aqueous solution of sodium hydroxide, or other suitable sodium compound, to form sodium benzene-sulfonate. This is separated from the solution, dried, and fused with solid sodium hydroxide, forming sodium phenolate together with sodium sulfite. The sodium phenolate is then treated with an aqueous solution of benzene-sulfonic acid, substantially free from sulfuric acid, forming phenol and sodium benzene-sulfonate, which may be separated by suitable means. The solution of sodium benzene-sulfonate is then evaporated to dryness and the dry sodium benzene-sulfonate then fused with solid sodium hydroxide, forming as before sodium phenolate and sodium sulfite. The sodium phenolate is then neutralized with a fresh charge of benzene-sulfonic acid, substantially free from sulfuric acid, forming as before, phenol and sodium benzene-sulfonate, and the process repeated. The sodium sulfite which is formed in the process is removed from time to time as may be necessary.

The reactions may be illustrated substantially as follows:—

$$C_6H_5SO_3Na + 2NaOH\ (\text{fused}) = C_6H_5ONa + Na_2SO_3 + H_2O$$

$$C_6H_5ONa + C_6H_5SO_3H = C_6H_5OH + C_6H_5SO_3Na$$

$$C_6H_5SO_3Na + 2NaOH\ (\text{fused}) = C_6H_5ONa + Na_2SO_3 + H_2O$$

ELECTROLYTIC PRODUCTION OF COAL-TAR INTERMEDIATES

The Society of Chemical Industry in Basel has worked out in a recent patent (Br. Pat. 15,750, Nov. 8, 1915) a practical method for effecting the oxidation or reduction of certain aromatic compounds, which are insoluble in the electrolyte. An essential feature is to have just enough difference between the specific gravity of the electrolyte, and that of the compound to undergo change or its solution in liquid which does not mix with the electrolyte, so that adequate emulsification is allowed in the immediate neighborhood of the active electrode. No diaphraghm is employed, and there is no wandering of the compound, undergoing treatment, to the other electrode.

In the case of the reduction of nitrobenzene to azobenzene, a vessel of sheet iron is employed, which widens downward to a funnel-shaped bottom lined with cement. This tank serves as an anode. The cathode consist of a cylindrical roll of layers of wire gauze. A hot mixture of caustic soda solution and nitrobenzene is kept in constant circulation through the meshes of the cathode by means of a high-speed rotary pump. The emulsion collects in the bottom of the tank

In converting azobenzene into hydrazobenzene, a cement tank is employed. It is charged with hot caustic soda solution, containing PbO. A solution of azobenzene in benzene floats on top. A flat electrode is suspended near the top of the liquid. A similar anode is at the bottom. Oscillation of the cathode causes emulsification. The oxygen, evolved at the anode, is led off by a wire sieve.

In the production of hydrobenzene from nitrobenzene, a similar ararngement is used, the position of the electrodes being reversed. The electrolyte consists of PbO and caustic soda. A heavy substance, such as dichloro-naphthalene, is mixed with the nitrobenzene.

A similar device is employed for the transformation of o-nitrotoluene to hydrazotoluene. Agitation of the solution below the cathode is effected by means of an external rotary pump.

In the operations described, PbO may be replaced by SnO or by ZnO. The reaction is under constant control. It can be interrupted with the transformation into an azo compound, or it can be prolonged into the hydrazo stage.

The Manufacture of Sulfonic Acids.

D. Tyrer (Br. Pat. 103,204; Jan. 12, 1916) prepares the monosulfonic acids of benzene and other hydrocarbons, boiling below 200°, by passing the vapor of the hydrocarbon through H_2SO_4 heated to 100°. By this method the H_2O formed is steadily removed from the reaction mass. In the preparation of disulfonic acids, the current of vapor is stopped when a given amount of the monosulfonic has been formed. More H_2SO_4 is added and the temperature is raised to the favorable point. It is noted that the unsulfonated portion of a hydrocarbon, treated by this method, has been freed from its impurities, notably from sulfur compounds, and can be condensed in a purified form.

IV

ARTIFICIAL COLORS

THE MANUFACTURE OF COAL-TAR COLORS IN ENGLAND

[The experiences of Great Britain in facing a dyestuff famine and how it was met are parallel in many respects to those through which the United States has passed. Yet, in certain connections there are distinct differences. The tale of these experiences, as recently given in the London Times, is at once interesting and instructive. The author of the first section is a prominent member of the staff of British Dyes (Limited). The author of the second section is anonymous.—Ed.]

I—POSITION ON THE OUTBREAK OF WAR

By C. M. Whittaker, B.Sc.

The coal-tar color position on the outbreak of war in August, 1914, may be very briefly stated by giving the Board of Trade returns of the imports of dyestuffs into Great Britain for the year 1913. They are as follows:

	Lbs.	Values
Aniline colors	31,699,024	$7,512,194
Alizarine colors	6,811,056	1,325,833
Indigotine	2,675,568	373,504
Indigo	467,488	266,578
Total	41,653,136	$9,478,110

It has been freely stated that business totaling annually $1,000,000,000, employing some 1,500,000 people, depended upon the above supply of dyestuffs. Of the above total imports, it was estimated that $9,000,000 was received from Germany; the balance was chiefly from Switzerland, except for a negligible import from France.

The number of qualified coal-tar color chemists in Great Britain was extremely limited, and the supply could not be extended without a considerable lapse of time.

British-Made Intermediates.

However, given the requisite labor and raw materials, there was a distinct nucleus upon which to commence building a national industry. Many of the important parent and intermediate products were being produced in Great Britain; both the plant and manufacturing experience were immediately available, though naturally not on the scale to meet the suddenly increased demand, due to the stoppage of the German supplies. The following list includes some of the most important:

Nitro-benzene: starting point for benzidine base, nigrosine, and induline.

Aniline oil: used for production of aniline black on the cotton fibre and with innumerable uses in color manufacture, including that of synthetic indigo.

Di-methyl-aniline: indispensable for basic colors, gallocyanines &c.

Para-nitro-toluene: for direct cotton yellows.

Para-nitraniline: for para-red (Turkey red substitute), and direct cotton colors.

Meta-nitraniline: for mordant yellow for wool khaki.

Di-nitro-chloro-benzene: indispensable for sulphur blacks.

Di-nitro-phenol: indispensable for sulphur blacks.

Meta-phenylene-diamine: for sulphur browns, direct cotton blacks and browns.

Alpha-naphthylamine: indispensable for acid and fast chrome blacks.

Sodium-naphthionate: for direct cotton and wool reds.

Anthraquinone: parent product for alizarin and vat colors.

Imported Intermediates.

On the other hand there were many products, of the greatest importance, which were not being made in Great Britain on the outbreak of the war:

Alpha and beta-naphthol: these two products had been made in Great Britain, but their manufacture had been dropped.

Beta-naphthylamine: used for bright blues and mordant yellows.

Di-anisidine: for bright sky blues.

Benzyl chloride: for acid violets.

Benzaldehyde: for malachite green and patent blues.

Anthrarufine: for fast to light wool blues.

Phthalic anhydride: for rhodamines, etc.

Salicylic acid: for mordant and direct cotton colors.

Representative members of every class of dyestuffs were being made in Great Britain with the exception of vat colors, but there were many gaps. Among the most important colors, apart from the vat colors, not being made in Great Britain by British firms the following must be named:

Alizarin blues (other than blue S), greens, and blacks.

Alizarin sapphirole and its allied colors.

Patent blues so largely used by the shoddy trade.

Direct cotton colors of outstanding fastness to light.

As a set-off against these it may be said that the British makers were very strong in sulphur colors, which are of so much importance in cotton dyeing, basic colors, acid colors and, fortunately, those mordant colors which were required for dyeing the wool for the khaki uniforms

In conclusion it may be repeated that the most serious factor in the color situation, on the outbreak of war, was the paucity of color chemists with actual experience in the manufacture of dyestuffs, a factor which only time can remedy.

It must not, however, be thought that all the above color was consumed in Great Britain, because a considerable quantity of color has always been brought to this country for shipment to the various mills in India, Australasia, and South America To the above must be added the production of the British makers, which was estimated to be worth approximately $1,000,000 or 10 per cent of the total imports

Recovery in England.

It is a mistake to assume that there was no coal-tar color industry in Great Britain All the world now knows that Great Britain started the coal-tar color industry, but that the industry gradually declined for reasons, which do not fall within the scope of this article, till it had reached its lowest ebb in the years 1898-1900. What is not, however, generally known is that from the latter date there was a gradual revival of the British industry, due to enlightened management, so that one British firm was in a position to pay 10 per cent. for several years prior to the war.

The following firms were engaged in coal-tar color manufacture in Great Britain in 1914:

The British Alizarin Company, Silvertown, E. This company was started by large users of alizarin red in Great Britain to fight the German Alizarin Convention. It was successful in its efforts, but confined its production to alizarin red, alizarin orange, and alizarin blue.

Levinstein (Limited), Blackley, Manchester.

Read Holliday and Sons (Limited), Huddersfield.

The majority of the shares in these last two companies were held by the respective families.

The above three firms were the largest British-owned concerns, and there were in addition some smaller concerns, such as Claus and Co., Clayton, Manchester, and Morris, Denton, which confined themselves to a very limited range of products.

Foreign Firms in England.

In addition to the above there were the following three works in Great Britain, but owned by Continental firms, viz:

The Clayton Aniline Company (Limited), Clayton, Manchester, which is owned by the Society of Chemical Industry, Basle.

The Ellesmere Port Works, Cheshire, which were owned by Meister, Lucius, and Brüning, Höchst on the Main; synthetic indigo was manufactured here.

The Mersey Chemical Works, Bromborough, Cheshire, were owned by the German combine of the Badische Company, the Bayer Company, and the Berlin Aniline Company. These works were largely used for storage purposes. Sodium hydro-sulphite was manufactured, but large quantities of color were not made at these factories.

The weakest point in the British position on the outbreak of war was:

The British firms had been in the habit of buying so many of the important intermediate products from the Continent.

II PROGRESS IN BRITISH DYE MAKING

[Anonymous]

Nine months ago, in the London Times, under the title "Peril of British Dye Industry—Vigorous Action Essential," not only was the situation of this branch of chemical industry fully considered, but the discussion was extended in subsequent articles to the broader problems involved in the utilization of our coal, particular stress being laid upon the conservation of the by-products obtained in coking coal, as these are the raw materials from which dyestuffs are produced.

Over and over again, during the period of the war, various writers conversant with the requirements have urged that unless wise Government action were taken without delay it would be impossible to effect the complete organization of our dye industry so that it may meet German and other rivalry in the future. What is far more important, the users of dyestuffs generally have been consistent advocates of such a policy.

Mr. Sharp, the chairman of the Bradford Dyers' Association, in his recent address to the shareholders, in once more calling attention to the urgency of our situation could only lament that, notwithstanding the insistent and persistent appeals of the accredited representatives of practically all the color users in Great Britain and Ireland, the necessary steps had not been taken to secure the consolidation of the manufacturing interests in a single company so as to prevent overlapping and waste of effort. Yet, owing to the increase in wealth of the United States, Japan, and Holland the competitive powers of these countries have been greatly increased. France also will wish to take a larger share; so that the task before us will be a far harder one than it ever has been or was supposed to be a year ago.

After-War Measures.

Aware of our determination, if possible, to be masters in our own house, Germany will leave no stone unturned to regain possession of the markets of the world; and it will only be by utilizing the technical forces of the country in the most effective and economical manner possible that we shall be able eventually to make a position for ourselves; hence the imperative need of organization.

Mr. Sharp sees clearly enough that immediately the war is over we must be able to offer the widest range of colors, but he does not seem to have realized what this entails. He gives illustrations showing what certain firms have done, from which he argues, optimistically, that there are no insuperable difficulties in covering the whole field of German production. Unfortunately, the production of a wide range of colors must be a task of the greatest difficulty, on account of the large number and variety of the materials to be produced, each entailing for its manufacture not one, but probably a whole series of processes.

In point of fact the situation is an altogether peculiar one, and its gravity may easily be underestimated. During the early period of the war the critical position in which we were placed was not at first apparent to consumers. While some looked for the speedy termination of hostilities, others argued that the prolongation of war would cause a general paralysis of all the industries in which dyestuffs play a part. At that time considerable stocks were held by the representatives in this country of the German manufacturers—probably a six months' supply.

When these stocks appeared to be exhausted and the end of the war came to be looked upon as remote, the demand for dyes did not fall off to anything like the extent anticipated, and a period of panic ensued. Even the more easily produced dyestuffs—certain acid reds, oranges, and yellows—were rushed up to 30 or 40 times their pre-war value. British Dyes (Limited) came into being during this period, as a new State-aided enterprise unconnected with the other firms then in existence.

Present Conditions.

About this time useful agreements were made with the Swiss color manufacturers, which led to raw materials and intermediate products being exported to Switzerland and returned as finished dyestuffs. The effect of this action and of the progress made by British makers was to render the position easier, and of late far less anxiety has been shown.

Although prices still rule very high, most of the color-using industries of the country have been able to adapt themselves to the altered conditions. The reasons why the prophecies of the pessimists have not been fulfilled are various. Recent events are an indication that even now some of the stocks referred to are not exhausted, as dyestuffs, perhaps purchased at the winding-up sales of German firms, are from time to time still being put upon the market. The very low prices prevailing before the war, and perhaps in some cases carelessness in regulating purchases, had led not a few to buy considerably in excess of their immediate requirements. Such hoarded supplies, in conjunction with the restricted volume of trade, have provided dyers with a surplus which they have either used themselves or exchanged with other consumers. Then some of the German vessels captured early in the war had dyestuffs on board, and several hundred tons obtained in this way have been brought to this country and sold by tender.

During the past 12 months supplies have been sent from Switzerland with fair regularity; a few consignments have also reached us from the United States. Consumers, too, have learned to help themselves in various new ways. Not only are old stocks previously considered almost valueless made use of, but economies are being effected by using old dye baths for further lots of material to a greater extent than before, and dyeing methods are being modified with a view to the more complete exhaustion of the dye bath. Where the requisite experience is available, dyers are often reverting to older processes and substituting for coal-tar dyestuffs the more readily procurable vegetable coloring matters. Two notable instances are those afforded by the increased consumption of natural indigo and the more extended use of logwood and its preparations for dyeing blacks.

Consequently, there has been no absolute dyestuff "famine." It has been possible, with a few exceptions, to dye any given material to a shade at least near to that required; the resulting color, however, frequently lacks some property which would have been considered essential in pre-war days, such as fastness to light, washing, or acids, or brilliancy or retention of tone in artificial light.

Quality of Dyes.

But the range of dyestuffs now available unfortunately lacks many of those which possessed the highest degree of fastness. Thus logwood blacks on wool are inferior in fastness, on exposure to light, to many of the coal-tar blacks in use before the war; very few of the alizarin dyestuffs, so largely used for the production of fast colors on woolen material and also of the highest importance in the calico-printing industry, are now obtainable, and those that are can be had only in very limited quantities.

On the other hand, although it must be admitted that the colors of most dyed materials are now less fast than formerly, one important exception is to be noted. The direct black dyes used for cotton have been largely superseded by the sulphur blacks, which withstand washing and exposure to light much better. The necessary intermediate materials for the preparation of these having been available in larger quantities it has been possible to produce them much more cheaply than formerly.

Until recently, with the exception of a limited range of Swiss colors, we have also been without supplies of the "vat dyestuffs," a class which (owing to their exceptional fastness in light and on washing) had come into great favor in the days just before the war.

An interesting proof that enterprise is not altogether lacking in the industry is afforded by the fact that one dyer has even gone so far as himself to undertake, and with complete success, to manufacture one or more of these vat dyestuffs for his own use. These dyes have been placed at the disposal of the industry only during the past few weeks, but already two of the British dye manufacturers are advertising their sale competitively—a foretaste of the manner in which our firms will support each other in developing their industry if it remain unorganized!

It thus appears that, though we have helped ourselves to some extent, we have been far better provided with German dyestuffs than is commonly supposed; it is difficult to say what the position would have been without these supplies.

Future Conditions.

Probably we shall be able to struggle on during the period of the war fairly well with the aid of the present limited supplies of coal-tar colors, aided by various substitutes and makeshifts. But are we to revert to the old conditions afterwards? Even if, as a nation, we are prepared to sink into dowdiness, our textile and other dye-using industries must have a full range of the highest classes of dyestuff, and unless we can obtain similar materials, either from our own manufacturers or from abroad, at least our export trade must suffer most severely. It is clear that if we cannot revert to the old conditions we must learn to help ourselves much more than we are now doing.

No better evidence of the demand that will arise in the future could be asked for than is afforded by recent sales. A direct blue dyestuff, known to yield a very pure shade of sky blue on cotton, was sold at nearly $34 per pound. A concentrated brand of a bright pink Rhodamine is worth nearly $48 per pound. These dyestuffs could have been bought for about 60 cents and 96 cents per pound respectively before the war. As soon as war is over dyers will not only be called upon, but they will naturally strive to recover their efficiency and meet all requirements; the demand for novelties will once more assert itself.

Marked as has been the progress of several of the British firms during the past year or so, evidence is before the public that there is much unnecessary overlapping; those who are more or less behind the scenes know that the energies of manufacturers are being wasted in many directions owing to the entire lack of co-ordination in the industry.

Thus two competing firms have devoted capital and much scientific-skill to the production of the vat dyestuff of the indanthrene class already mentioned. A coloring matter of only secondary importance, methylene blue is being offered by five distinct firms, two British and three Swiss.

We know that the German makers have combined all their forces with a view to economy and efficiency in all branches of their work, including the interchange of intermediate raw materials. Here in recent times difficulties have been placed by one firm in the way of another, and much of the effort needed to build up a comprehensive and extended industry is being wasted in unnecessary repetition.

But there are other directions in which British dye manufacturers have to make up much leeway, in which there should be cooperative action. The German firms have, at all times, sought to aid the dyers and to secure their sympathy as well as their custom—they have sought to deserve custom by rendering all possible assistance to buyers.

Necessary Reforms.

The rendering of expert assistance of this kind should be made a stronger feature of the British color industry. Colors now being made are not identical with those which will be supplied after the war, but help given now, to the extent permitted by a reduced staff, will be amply repaid in the future. A firm grows accustomed to turning to a definite quarter when in difficulties.

The consumer must also help the manufacturer. This theme is merely the converse of the last. All information which the consumers can give to the manufacturer with respect to his methods and difficulties is of service in the search after improved products. Color users can also render great assistance by permitting trials with new dyestuffs on a practical scale to be made in their works.

In future, too, our color-makers must not rest content with mere imitations of the German dyestuffs previously in use, but must continually try to improve upon their foreign competitors; the possibility of success in this direction will depend, of course, largely on the presence in the works of the right kind of chemists with the right kind of training.

Dyers must contemplate during the first few years some slight financial sacrifice, though in hundreds of cases the actual cost of the dyestuffs is but a fractional percentage of the value of a finished article. In every case the use of a British dyestuff, even at a few cents more per pound while the color industry is being established here, may be considered but as the payment of a very low premium, indeed, on a policy which will eventually ensure us against a recurrence of the present ruinous conditions.

The Chairman of the Bradford Dyers' Association in his speech. expressed his confidence in British chemists, and there is no reason to doubt their ability to solve all the problems of the industry—given sufficient time. But there are not nearly enough of them for the work, which is of very special difficulty in its higher branches—not a tithe of the necessary number. The men who can develop such an industry are of an unusual type, born and not to be easily picked out; they are destroyed rather than developed by our system of education. To introduce foreign workers would be a fatal blunder and a grave discouragement to our schools.

Past Errors.

Unfortunately, too little has been done during the war to make efficient use of the more skilful among our chemists in developing our national efficiency as chemical manufacturers. Far too many have been set to work as laboratory hacks to make pharmaceutical preparations on a Lilliputian manufacturing scale. The proper course would have been to have allowed each of the more competent to build up gradually the nucleus of an industrial manufacture of some particular article. instead of a number all doing more or less the same thing.

In this direction. as in many others. we have gone astray through our failure to apply scientific method to our affairs and to organize our efforts.

It is easy to complain that Government has been short-sighted and will not take advice, but reflection shows that it could not well have been otherwise, in view of the general ignorance of every detail of the problem. What we have to complain of is the blank impassiveness of the official mind which leads it to put aside all advice—to pay no regard whatever to expert opinion.

But the beam in the scientific eye must not be overlooked. Far worse, than any failure of the Government is the failure of the representatives of science to organize themselves so effectively that whatever advice they might have tendered would have been so weighty that it could not have been put aside.

The question now is: Are we to the bitter end to court the failure we have so long invited? Mr Sharp spoke out very plainly in saying that he and his colleagues, in common with other color users held most strongly that the Government should by some means compel British color-makers to coordinate their efforts, and that we shall not attain the object we have in view unless the only step which can bring us to it be taken. No one who understands the situation can hold any other opinion, but the co-ordination must be far-reaching and complete.

GROWTH OF THE COAL-TAR COLOR INDUSTRY IN OTHER LANDS

A World-Wide Attempt to Secure Emancipation From German Sources.

[The following review, in the London Times for April 15, 1917, of the progress being made in other European countries. and in Japan, to ensure independence in the supply of artificial dyestuffs, shows how general and determined is the conviction abroad that it is an economic sin to allow a nation's textile and allied industries to be chained to a single source of the vital factor of color. —Ed.]

German artificial-color makers confidently predicted that their huge output of high explosives would bring about the early collapse of France and Russia, and that the lack of German dyestuffs would lead to the stoppage of the British textile industry and prove one of the factors that would force England to a humiliating peace. In any event these predictions are already falsified, and one of the results of the war will be the enfranchisement of the textile world from too complete dependence on Germany for artificial dyestuffs. There is a world-wide effort to establish the coal-tar color industry locally, and a potent factor for the success of the endeavor in each country is that the close relationship between color making and the manufacture of high explosives is as last fully recognized.

Switzerland.

Switzerland, next to Germany, is the largest producer of artificial colors. She was largely dependent upon the Fatherland for the raw materials of the industry and supplies were quickly stopped. With the aid of France and England this difficulty has been overcome, and although the Swiss Army is mobilized. and in consequence there is a shortage of labor. Switzerland is now sending out satisfactory quantities of dyestuffs, including some of the modern and very fast colors known as the vat dyes. As opportunity offers it is certain that the Basel works will be greatly developed, and it is probable that Swiss progress will be ensured by an entente with the British and French manufacturers.

France.

France had only one native artificial color works at the commencement of hostilities, the Société des Matières Colorantes de St. Denis. The Compagnie Parisienne de Couleurs d'Aniline at Creil and the Manufacture Lyonnaise de Matières Colorantes at Lyons, in spite of their Gallic names, are branches of German works, both still operating under government control. The St. Denis works, asociated with the name of Alcide Poirrier, who died recently, has had a long and honorable career. Poirrier almost immediately followed up Perkin's discovery and commenced the manufacture of coal-tar colors. Many important new colors were discovered at St. Denis, among others the highly important sulphur black. In spite of the difficulties of the times, the St. Denis works has modernized its plant, and important extensions are contemplatd.

Our Government support of British Dyes (Limited) has led to a similar movement in France. The Société Nationale des Matières Colorantes has been formed with a capital of 40 million francs, a syndicate with government support guaranteeing one million francs. The society will instal at its own cost in the Oissel Powder Works and other state explosive factories the plant necessary for the manufacture of the chemical and coloring matters required by the French industries, and for the explosives, chemicals or colors required by the Ministries of War and of Commerce. The society will deposit 500,000 francs in French securities with the Bank of France as a guarantee. The duration of the concession granted to the society is 18 years, and it is at liberty to relinquish it after 12 years. By the terms of its contract the society engages, as far as possible, to make all the chemicals and coloring matters required by the French textile industries. It is understood that certain arrangements have been made between this French National Company and British Dyes (Limited), probably as regards the provision of raw material and to avoid overlapping.

Another new company, with a capital of three million francs, is the Compagnie Française des Produits Chimiques et Matières Colorantes de Saint Clair du Rhône. As a director of the National Company is on the board, it is surmised that there is an entente.

Italy.

In Italy matters are less advanced, but the Italian National Dyestuff Company has been founded with a capital of six million lire ($1,154,000). The most important Italian financiers and the heads of the chemical industry have assisted. The value of the annual importation of German chemicals into Italy has been 30 million lire ($5,790,000).

Japan.

Japan is now independent of foreign supply in the important items of aniline oil and salt. The dyestuff industry has been fostered since the outbreak of the war; the total value of dyes annually imported into Japan previously amounted to $4,000,000. The Tokyo Gas Company, the Mitsui Mining Company, and a few others have succeeded in manufacturing artificial dyes successfully, and are learning rapidly. Sulphur dyes, including black and browns, are not yet fully perfected, but their production has been fairly large. The Japan Dyestuff Company, which was launched some time ago under official protection, will also start the manufacture of some special description of dyes at its own factories, which are now being completed.

Russia.

Russia made an early attempt to organize a dyestuff industry. Some progress has been realized, and arrangements have been made to engage chemists from the friendly countries, notably Switzerland, but the effort still hangs fire. A company, with a capital of $2,125,000, has been formed at Moscow to produce benzol.

[At the close of this review a tribute is paid to the recent dyestuff census, compiled and published by the American Department of Commerce. A portion of this is reproduced below.]

The United States has gone into the question thoroughly and systematically. A dyestuff census has been prepared and published by the Bureau of Foreign and Domestic Commerce. This is an enumeration of the dyes imported into the U. S. A. from Europe during the year preceding the war, and is published to assist American manufacturers in estimating the normal demand for each individual color. The extent to which most colors have been used in the country has in the past been known only to the importers of the foreign product. It was recognized that an intelligent effort to build up a comprehensive, self-contained American coal-tar industry must rest upon the solid foundations of accurate statistical data concerning the American market for artificial colors. In no other way can the creators of such an industry avoid overlapping and tentative struggles to adjust productive mechanism to a vague, indefinite demand. In the dyestuff census the Government has gathered together the statistics required. The work was compiled from the Customs documents in the possession of the Treasury Department, and several months were required by Dr. Norton, the author, and a staff of clerks to assemble and tabulate the data. It is the first time that a census of colors has been compiled by any government. The exact title of the report is "Artificial Dyestuffs used in the United States," Special Agents Series, No. 121. It contains 219 pages of statistical matter, and in addition an elaborate text. The total annual consumption of the U. S. A. is returned as 42,839,052 lbs., against a total annual importation of 41,653,136 lbs. by Great Britain, part of which is re-exported. In a masterly analysis of this census by Mr. C. M. Whittaker, of British Dyes (Limited), it is pointed out that although it has been stated that the Germans make their profits by the patented colors it is in fact the simple colors that are required to keep the textile trades in full swing. Many more dyers are held up for lack of the bread and butter dyes than for want of specialities.

The importance of the American inquiry to other countries depends on the fact that there is a certain parallelism in the consumption of the diverse countries, so that from the American consumption of a particular color an approximate idea may be gathered of the British and French consumption of the same color.

The French consumption of artificial colors is estimated at 9,000 tons annually, worth about $5,000,000; the English consumption may be gathered approximately from the American census, at any rate with a sufficient exactness to arrive at the relative importance of a given color, and to determine whether it is worth while to manufacture it.

A NEW METHOD FOR THE USE OF CHROME MORDANT

In the prevalent methods for using the chromates as mordants to fix various artificial and natural dyes upon textile fibers, it is customary to treat yarn or fabrics with a solution of a chromate—usually potassium dichromate,—and then introduce them into a bath containing the color in solution. The operation is conducted in the presence of a reducing agent, such as a tartrate. The sequence of the treatments is often reversed. In whatever order the successive steps of the operation are performed, great care, and much labor and time are involved. Otherwise a certain waste of coloring matter ensues. Under the most favorable conditions, there is a tendency to weaken and harden the fiber.

Dr. William Beckers and Dr. I. Dreyfus of Brooklyn, N. Y. (American Pat. 1,228,089, of May 29, 1917), have devised a new and simple process, by which the disadvantages of the current methods are materially obviated.

They find that if neutral alkaline chromates are dissolved in a strong solution of glucose. and this is added to an aqueous solution of logwood, alizarin blue, or similar natural and artificial colors, a chromium compound of the latter is obtained which is perfectly soluble in water. Textile fibers, introduced into such a solution, absorb the compound with perfect ease; the penetration is complete; and a permanent, insoluble combination between the fiber and the mordanted color is effected.

The following example illustrates one method of applying the new invention: "Dissolve 108 pounds of glucose in 216 pounds of water and gradually add 55 pounds of neutral sodium chromate with constant stirring, maintaining a temperature of 80° to 90° C. Heat until the presence of chromic acid cannot be detected by an acidulated solution of potassium iodide. The whole operation generally requires from three to six hours. Introduce acetic acid, which requires about 20 pounds of acetic acid of 70%, to neutralize the alkali liberated. To the solution of the chromium compound thus formed, add a solution of 2,100 pounds alizarin blue, 20% paste, in sufficient water, with constant stirring. The resultant clear solution of the chromium compound of alizarin blue may be used directly in the dye bath with the addition of the proper dyeing accessories, such as acetic acid or sulfuric acid.

Not only can such a solution be used directly as a dye bath, but it can, also, be evaporated to dryness, after being rendered slightly alkaline. The dry color compound, thus obtained, is readily soluble in water, and its solution can be used in the same manner as the original solution from which it was separated.

This new process, if sucessful, will notably simplify operations for the prospective manufacture of a large number of soluble mordant colors for household use.

COAL-TAR RESEARCH AT HUDDERSFIELD.

The local authorities at Huddersfield, a leading center of the English dyeing interests, have taken active steps to establish, in connection with the Technical College, extensive laboratories for research in coal-tar chemistry. Generous support in the way of subscriptions shows that the project meets a wide-felt need.

THE WAR-TIME UTILIZATION OF GERMAN COLOR PATENTS IN GREAT BRITAIN.

The British Comptroller of Patents is authorized by law to grant permits for the use, during the war, of processes covered by patents owned by enemy aliens. L. B. Holliday & Co., of Huddersfield, recently applied for licenses to operate under 19 valid patents issued to Germans, and connected with the manufacture of coal-tar dyes. A royalty of 2½ per cent. on the selling price will be paid by the licensees.

AMERICAN SYNTHETIC INDIGO.

There is a genuine feeling of pride among American chemists over the perseverance and energy displayed by the Dow Chemical Co., of Midlands, Mich., in successfully overcoming a multitude of difficulties and obstacles, and permanently establishing in our country the manufacture of artificial indigo, the most important of all the coal-tar colors. The daily production had attained 1,200 lbs. of 20 per cent. paste on June 1, and the output is steadily increasing. The above figure is equivalent to an annual production of about 186 short tons. Prior to the war the annual consumption of artificial indigo in the United States was somewhat over 4,250 tons.

NEW DYE DISCOVERIES REPORTED.

Curiosity is growing over the reports regarding the discovery of two important dye processes that are expected to prove valuable to this country in its efforts to build up a home industry in aniline dyes and coal-tar products. The discoveries were made by a chemist in the dye plant which has been established by the Bureau of Chemistry of the U. S. Department of Agriculture, at Rosslyn, Va., and although it is desired to prove its commercial practicability before issuing an official statement, it is believed that a dye which has heretofore been very expensive can now be manufactured for a fraction of its previous cost.

V

NATURAL DYES

THE PRESENT POSITION OF NATURAL DYES IN BRITISH INDUSTRIES

[Great Britain was forced, during the present war, at a much earlier date than the United States, to resort extensively to the use of natural dyestuffs. An English expert recently contributed to the columns of the London *Times*, the following valuable study on the present position of this category of coloring materials.—Ed.]

Indigo, madder and logwood were the mainstays of the textile colorist before the advent of the artificial coloring matters. Madder, second in importance of these, has been entirely replaced by synthetic alizarin in dyeing Turkey red on cotton, and is used to a very limited extent in wool dyeing. The exports fell from over 5,000 long tons in 1868 to a little more than 200 tons in 1892.

Indigo has always been regarded as the queen of dyestuffs. As late as 1897 the Board of Trade returns showed that the value imported into Great Britain exceeded that of all the aniline and alizarin colors of every description. It was hurt badly by the more general adoption of khaki and field-gray in uniforms Since the discovery of a satisfactory commercial process of synthesizing its principal coloring matter, indigotin, it has been left to some branches of the woolen dyeing industry. As in the case of madder, the synthetic substitute is much easier to use, but in the case of indigo the natural product contains other tinctorial matters, in addition to indigotin, which for this reason will probably never entirely supersede it. Since the war it has been eagerly snapped up as it came on to the market, and quickly came under Government control. The Indian planters and merchants have been urgently advised to send it out in a form more nearly approaching that of the synthetic product, and as a readily useable paste or powder it will have better competitive chances.

Logwood is the most important of the natural dyewoods and has best held its ground. It gives various colors with the mordants. In this way with bichromate it gives blue and black, with iron black, with copper olive and greenish black, with aluminum salts violet blue, and various other tints with other mordants. Before the days of the artificial coloring matters it was largely used for all these tints, alone and in combination with other dyes, but latterly its employment has been chiefly confined to the production of incomparable bloomy blacks. Logwood extracts and haematin, the coloring principle extracted from the wood itself, have been put on the market, and since the war began have been put to many of their original uses as polygenetic dyes.

Natural Colors in Chief Demand.

Although coloring matter is largely distributed in the vegetable kingdom, the number of natural colors employed before the days of the coal-tar dyes is surprisingly small. In addition to the three mentioned there were peachwood, camwood, barwood, saunderswood, orchil and cudbear, fustic, fustet, weld, quercitron, Persian berries, turmeric, cutch, sumac, and a few other tannins. Most of these have survived the competition of the coal-tar colors, if for restricted uses only. Since the war they have been eagerly in request. In the States some inferior and despised dyes, such as Lima wood, known as hypernic, have come again into vogue. The osage orange-tree, long known as a dye locally and very like fustic in its properties, has found employment and has been prepared as an extract known as aurantine.

As regards natural coloring matters, it is this question of collection that is often the crucial point. One of the most persistent questioners in Parliament, during the early days of the war, pointed out that it was notorious that an infinite number of plants yielded dyes, and asked why the British fields could not serve the needs of the dyer. In some cases, but for the difficulties of collection, British natural products would be available. Take privet, for instance. It gives a fair yield of a coloring principle, very similar to that of fustic. But all the privet in the kingdom would not go far. In competition with fustic it could not be cultivated to advantage.

A natural coloring matter, in order to come into commercial use, must be available in large quantities and stand a competitive test in other respects with the dyestuffs that have been proved by centuries of use. This is why the long lists of natural dyestuffs, in local employment all over the world, that have lately been given in technical publications, are almost solely of academic interest. India, in particular, teems with native dyes, but they have all been tried long since, and most of them condemned. Some, like kamala for instance, are of great beauty, but of little permanence. Others are too inaccessible. The bulk of them are similar to dyes in ordinary use, but poorer in coloring principle. The same objections apply to the dyes used in the Highlands, excellent for local uses, but for one reason or other not marketable.

Eastern Dyes and Methods.

The excellence of Eastern results in dyeing and printing, Persian carpets and Javanese batik work for instance, is often pointed out as a proof of the superiority of their natural coloring matters. The fact, however, is that the dyes used are the same and similar in their coloring principles to those in the list above There are several madder-like plants in the East, for instance, and local varieties of indigo. The superiority is mainly attained by the slow, laborious handwork, which modern conditions no longer permit in the West.

One result of the war has been the awakening of the public to the fact that the use of natural colors does not necessarily imply fastness, and that, on the other hand, the coal-tar colors are neither necessarily loose nor garish. The disappearance of some favorite tints and the inability to guarantee colors as fast to washing have been educative.

The demand for natural dyestuffs since some classes of coal-tar colors have been unobtainable is best shown by the Board of Trade returns. It is estimated that the output of dyewood extracts has been trebled during the war. Our imports of extracts for dyeing have risen in value from $673,676 in 1914 to no less than $3,265,315 in 1916. The following table shows our imports of dyestuffs and dyewoods during the last three years:

IMPORTS INTO THE UNITED KINGDOM.

	1914		1915		1916	
DYESTUFFS:	Lbs.		Lbs.		Lbs.	
Cutch	6.671,616	$393,168	10.284,736	$641,661	14,698,656	$1.256,141
Extracts for dyeing	*	673,676	*	1,686,344	*	3.265.315
Indigo	595,168	884.844	2,807,584	6,120.177	3,417,456	7.081,958
Unenumerated	16,831,472	1,636,590	31,379,600	7,111,977	30,355,136	10.949,074

NATURAL INDIGO

As one result of the great war, it is possible that there may be more of a commercial future for natural indigo than has been the case since the beginning of the present century, and the advent of the synthetic product.

The great advantage of the latter is due to the perfect uniformity of tint, and the equal uniformity of strength. The most common form in which artificial indigo appears on the market is that of the 20 per cent. paste. The dyestuff contains exactly 20 per cent. of indigotin, and is free from any admixture of closely allied tinctorial matter.

The natural indigo of India and other Oriental lands, as well as of Central and South America, is of the most variable composition. The indigotin content ranges from 20 to 60 per cent. The indigotin is, furthermore, accompanied by varying amounts of other more or less closely allied tinctorial substances, the most notable of which is isomeric indirubin. As a result the dyer is unable to use the natural dye with absolute certainty as to quantity required, and as to uniformity of shade.

It is an open question whether, apart from the above considerations, indigotin can be obtained most economically by synthetic processes, or by the cultivation of the choicer varieties of *Indigofera*.

The cessation of all export of artificial indigo from Germany has, naturally, stimulated a vastly increased production of the natural dyestuff in India, and in adjoining lands, where the cultivation of the plant has been continued to some extent, despite the competition of the Occidental, synthetic product. Thus, during the season of 1915-16 the acreage devoted to indigo culture in India increased by 112 per cent., while the increase in the export was 145 per cent. During the past season the exports show an increase over 1915-16 of 24 per cent.

The question has arisen as to the possibility of perfecting and standardizing the Oriental product, so as to do away largely with the conditions which permitted so easy a conquest by the coal-tar competitor.

It has been taken up actively and intelligently by the Indian government. Experts have been busily occupied with the requisite researches. As a result it has been found feasible to produce a standardized paste, containing 18.9 per cent. of indigotin, free from many of the disadvantages enumerated above. A half-ton of this paste is now being thoroughly tested by various dyeing firms.

There seems to be little or no doubt that a standard paste, of uniform strength and tint, can be regularly produced in India. Interest now centers about the possibility of placing it upon the market at a price enabling competition with the German and Swiss artificial indigo, upon the return of normal industrial conditions. The problem depends essentially upon a distinct increase in the amount of indigo plants produced per acre, and, also, in the quantity of indigotin extracted from the plants.

The solution of the problem will result, apparently, from the cooperation of the bacteriologist. Indigotin is not present as such in the indigo plant, but as the glucoside of indoxyl, the so-called indican. From this combination it is liberated by the action of dilute acids or of certain enzymes and subsequent oxidation with atmospheric oxygen. Bacterial investigations are now under way in regard to a systematic control of the process of fermentation which takes place in the steeping vats.

Great variations in the yield of different factories from plants grown under similar conditions of soil and climate have been found to be due to the presence or absence of specific bacteria which infect the vats. The task for the scientist is to ensure artificially the presence of the beneficial organisms and the elimination of those which are deleterious.

It would certainly be a novelty in the history of chemical technology should India recover her oldtime supremacy as a source of indigo, after an interruption of a score of years, as a direct result of the world conflict, and with the cooperation of our modern, highly-perfected methods of bacteriological investigation.

One is tempted to inquire, whether there might not be a similar return of madder to its former position, as a commanding factor in the tinctorial world, should the process of fermentation by which alizarin is liberated from the glucoside, Ruberythric acid, present in the madder root, be subejcted to careful bacteriological investigation.

The possibilities of natural indigo should not be overlooked in the United States. Nearly two centuries ago the culture of the indigo plant was introduced into Georgia and South Carolina by an enterprising woman. Climate and soil seemed to be peculiarly propitious. By 1776 the export of American indigo to Europe had assumed notable proportions. The War of the Revolution brought the industry to a sudden end, and it has never been revived.

$135,000 Extension for Schoellkopf Co.

Plans are being completed by the Schoellkopf Aniline and Chemical Co., Buffalo, N. Y., to build a $135,000 extension. The new structures comprise an ice plant and factory and machine shop.

SAYS U. S. ARMY HEADS DISCRIMINATE AGAINST VEGETABLE DYES.

Because, he declares, the depot quartermaster in Philadelphia showed discrimination in favor of coal-tar dyes and against vegetable dyes for use in dyeing khaki, C. R. Delaney, of J. S. Young & Co., manufacturers of the latter class of dyes at Hanover, Pa., has voiced a vigorous protest in behalf of vegetable dye manufacturers in general.

"We require the use of coal-tar dyes instead of vegetable dyes," the quartermaster is quoted as replying to an inquiry from Mr. Delaney. In protesting against this ban on his product, the latter avers that "while it is possible that our American manufacturers of coal-tar dyes have not been able to imitate the German in respect to artificial khaki colors, nevertheless there are millions of yards of khaki cloth dyed with natural colors, both mineral and vegetable, that have never seen the inside of a coal-tar color works."

He further points out that quercitron bark extract which is the base color for dyeing khaki by the vegetable process, is manufactured in this country on a scale which makes coal-tar color production look small in some respects. Flavine is said to be even more powerful than some of the synthetic dyes, and before the war German and Swiss makers of fast yellows, according to his statement, bought 60 per cent. of the output.

VI

SYNTHETIC DRUGS AND PERFUMES, PHOTOGRAPHIC DEVELOPERS

SYNTHETIC PERFUMES

Possibilities of English Manufacture.

By Ernest J. Parry, B.Sc., F.I.C.

[Prior to the war the manufacture of synthetic perfumes, largely from coal tar derivatives, was steadily increasing in quantity and broadening in scope. The following study on the posibilities by an English authority, portrays, to a great extent, the nature of the problem to be faced, if American chemistry creates its own independent, artificial perfume industry.—Ed.]

In considering the degree of success which has been, or is likely to be attained in the manufacture of synthetic perfumes in this country, a proper conception of the meaning of "synthetic perfume" is absolutely necessary.

There are three different classes of bodies to which this term is applied indifferently by the layman, and more or less carelessly by the expert. To each of these three classes entirely different considerations apply. In the first place there is the true synthetic perfume, that is, one that has been built up from comparatively simple substances by chemical means. Secondly, there is a group of artificial perfume bodies, which, truly, are synthetic, but not in the same sense as the first class. They are bodies which by more or less simple chemical means are manufactured from other compounds, complex in their nature, which are found already existing in other perfume materials. The third class, which may be dismissed without serious consideration, are merely mixtures of natural with synthetic perfumes.

Two Principal Classes.

The two serious classes of synthetic perfumes may be illustrated by the following examples. Benzaldehyde, a synthetic manufactured from coal-tar products, is a faithful representative of the almond odor; phenylethyl alcohol is also made from coal-tar sources, and is an indispensable ingredient in artificial rose odors. These and hundreds of others belong to the first group above mentioned. But clove oil contains a substance, eugenol, in itself of very complex constitution, which can be transformed by chemical means into vanillin, the true artificial representative of the vanilla odor. The essential oil of the lemongrass contains citral, which is, in similar manner, transformed into ionone, the basis of all the artificial violet perfumes.

Now in dealing with these two groups of synthetic perfumes, the following points have had considerable influence on the question of manufacture in this country. There is in the first instance the lack of skilled labor available; secondly the lack of co-operation; and thirdly the lack of experienced business men with a full appreciation of the value of the trained technical chemist.

There have been highly successful attempts to manufacture a number of these synthetic perfumes, and those firms who have undertaken their manufacture will no doubt reap a rich harvest later. But efforts to manufacture one or two of these articles are hardly likely to be successful, as the expense of rent, wages, and plant cannot be met unless the factories are working regularly on a number of bodies, and so ensuring a continual output and turnover of capital.

Manufacture in England.

Taken as a whole, this country has not placed itself in a position seriously to compete with the German trade in these articles, nor, except in a few isolated cases, have serious attempts been made to do so. The industry is a large one, and an attempt to capture a share of it should be made by British manufacturers. But it is a business in which nothing but the highest skill and incessant industry will ever win success. So far as one can foresee, a much closer cooperation between the technical chemist with special knowledge of the subject and the business man who is intent on building up this industry is necessary. Committees of pure scientists, Government subsidies, and the like are all very well, but will not be the sine qua non of success. The business man must realize the inter-dependence of many branches of chemical industry and must realize that German success has been built up by using to the full this inter-dependence under the advice of armies of skilled chemists.

The want of raw materials, such as benzyl chloride, benzaldehyde, the cresols, magnesium, potash, and many others, has, of course, seriously handicapped the starting of this and similar industries, and Germany had created almost a monopoly for herself in these and many other articles. The electrolysis of our salt produces the chlorine, and we have a good supply of toluene in our coal-tar. These two bodies will produce all the benzyl chloride we require, especially as the conditions become more normal. And careful examination will show that all raw materials can be obtained by the proper exploitation of our resources.

There are no valid reasons why the synthetic perfume industry should not be as large in England as it bids fair to be in France. At present, unfortunately, the actual efforts made, important and successful as they are, are not commensurate with the possibilities of this attractive branch of chemical manufacture. In France there has been formed, under the auspices of the Ministry of Commerce, an "office of chemical and pharmaceutical products," whose work in moderating the effects of the shortage of raw materials and in generally assisting the development of the chemical industries is very highly appreciated. When one considers the enormous expansion in chemical works and apparatus that the manufacture of explosives has rendered necessary in this country, the thinking chemist is astonished at the lack of foresight in considering what the future of these works is to be.

SYNTHETIC DRUGS OBTAINED FROM COAL TAR

[The following article by a British physician gives an admirable portrayal of the evolution of an important class of highly valuable therapeutic compounds, from various coal-tar colors—the most brilliant triumph of recent chemical synthesis.—ED.]

The history of the relationship between the dye industry and modern scientific medicine is one of the romances of the industrial era. It is, indeed, a remarkable circumstance that the most potent of all the remedies which have been introduced during the last few years, and not only the most potent, but also the most precise and accurate, should be almost without exception, members of the great family of aniline derivatives. Even today, when the thing is an accomplished fact, people express surprise that anyone should have thought of looking in this group of chemicals for therapeutic agents.

The answer to this question is that the investigators who first dealt with these aniline compounds as medicines were attracted to them just because they were dyes. Modern pharmacology, the science of drugs and their action, desired to establish in what manner medicines acted, upon what parts of the body exactly they exercised their effects, and what changes they brought about by their presence. Obviously one of the simplest ways of answering these questions was to use some dyestuff which would leave traces of its presence behind it in the animals experimented upon.

That was one aspect of the investigation; the other was dictated by the fact that it was desired to find some substance which would act as a substitute for quinine. The result was antipyrine. Other potent drugs having the power, like quinine, of reducing temperature and alleviating pain were the synthetic aniline compounds known as acetanilide and phenacetin.

Pioneer Work.

At this point there came into the field that very brilliant worker, Paul Ehrlich, with whose name the aniline drugs will ever be associated. He came opportunely. The Germans had practically captured the dye industry and were devoting all their efforts to develop it. Ehrlich was given every opportunity, and his wishes in regard to new compounds were eagerly carried into effect. He had the whole industry, literally, at his disposal.

Ehrlich set to work with tremendous energy and soon formulated the generalization that each of his dye-drugs had specific medicinal properties which were peculiar to it, and were intimately related to the chemical constitution. Thus, if the structure of any dyestuff was altered the effect of the dye as a drug was altered also. He was able to show that each tissue responded in a special way to each dye, and that that response was specific for and characteristic of that tissue. Out of this arose the remarkable development in microscopic staining from which the sciences of histology, and, more important still, of bacteriology, have derived such immense impetus. Ehrlich showed that methylene blue when injected into the living animal was able to "pick out" the nerve endings in various structures while it did not stain other structures in the neighborhood. The advantage of this quality from the point of view of the student needs no emphasis. Again, Ehrlich showed that if tubercle bacilli were stained with fuchsin or methyl violet in the presence of aniline oil, they were able to hold the stain, even against the action of a concentrated solution of sulfuric acid. Other bacteria could not hold the stain against acids, and thus it was possible to distinguish the tubercle bacilli easily in any specimen. They alone retained the stain and could be picked out with certainty. For this reason tubercle bacilli are now commonly spoken of as being "acid fast." The discoverer of the tubercle bacillus, Koch, said it was entirely due to Ehrlich's work that the method of determining the presence of tubercle bacilli had been rendered so easy and certain, that almost anyone who cared could carry it out. A further effect of this work upon stains was the ability to distinguish the various kinds of white blood corpuscles, the "warrior cells," and from that investigation has arisen the important science of haematology.

The success of this work naturally encouraged other efforts. Ehrlich began to attack the problem of the diseases due to "trypanosomes," of which tsetse-fly disease and the human "sleeping sickness" are important examples. Mice were inoculated with the trypanosome of "mal de caderas," a South American trypanosome disease of horses, and Ehrlich soon showed that the dye trypan red,[*] a benzidine compound, was capable of killing the trypanosome in the mouse, and so of curing the animal. The dye had no ill-effect upon the mouse's own tissues, although the whole animal was stained red for months.

Important Discoveries.

This was a very important discovery, for it foreshadowed the new doctrine of specific effect, *i. e.*, that a drug must affect only one definite kind of structure, and not all the structures. It must be able to seek out germs of a special kind in a man's blood and kill these germs without in any way affecting the tissues of the man himself. The next application of this principle was the treatment of the disease of cattle and dogs known as "piroplasmosis" (because of the presence of a minute micro-organism, the piroplasma) by means of another benzidine dye, trypan blue,[†] an improvement on trypan red introduced by the French workers Mesnil and Nicolle. The piroplasma is introduced into the animal's body by means of a tick. This discovery has naturally and necessarily had a very great commercial value. The names of Sir S. Stockman, of the Board of Agriculture, and of Professor Nuttall, of Cambridge, are associated with this work.

Meantime at the Liverpool School of Tropical Medicine efforts were being made to use atoxyl (an organic aniline compound of arsenic) for the treatment of sleeping sickness. A modified success resulted, but unhappily the drug proved dangerous because of its effect upon the nerves of the eyes, and its use has been practically abandoned.

Ehrlich also showed that methylene blue was capable of curing certain varieties of malaria. He then began the labors with which his name will be for ever associated—the search for a cure for syphilis. His working motto was *corpora non agunt nisi fixata,* and keeping this dictum in view he tested some hundreds of organic arsenical compounds. His work brought him at last to the famous yellow dye, a derivative of a mother substance like benzidine, but with arsenic in the molecule, which he named "salvarsan," and which is popularly known as "606"—its serial number. This drug is a specific cure for syphilis, because it kills the *Spirochaete pallida,* the germ of the disease; it has also proved to be a specific for the tropical diseases, relapsing fever and yaws.

Dye-Drugs.

Salvarsan was the key-stone of the edifice of the dye-drugs. Salvarsan proved that the idea that it was possible to obtain drugs which would kill germs, and not in any way harm the bodies of the persons affected by these germs, was no chimera, but a true scientific conception. This idea of specific action has borne very valuable fruit. At the Middlesex Hospital Dr. Browning, a former pupil of Ehrlich and director of the Bland-Sutton Institute of Pathology, worked out a method of discovering the presence of typhoid bacilli in specimens of water and other fluids, such as the intestinal contents, where numerous other germs are also present. This depends on the fact that the triphenyl-methane dye, brilliant green, exercises a remarkable destructive effect upon the bacillus coli of the bowel, but little or no effect upon the bacillus of typhoid fever. If brilliant green was added to such a mixture of a few typhoid bacilli along with abundant colon bacilli, then all the germs present except the typhoid germ were destroyed, and the recognition of the typhoid organism was rendered easy and certain.

Perhaps the most striking of all the examples of specific effect was found in Ehrlich's "pyronin," which had an effect, not only on one particular kind of germ, but actually upon one particular part of a particular germ. Thus the germ known as the trypanosome to which reference has been made (the parasite of sleeping sickness), has two nuclei or "nerve dots" in its substance. One of these nuclei is situated in the tail of the germ, and so is known as the caudal nucleus. It was found that if mice were inoculated with this germ and then injected with pyronin, the caudal nucleus disappeared from the germs in the mouse's blood. Strangely enough, the other nucleus did not disappear, nor did the germs lose their power for evil. Thus it was clear that this pyronin had a specific effect upon an infinitesimal particle of matter in the body of an infinitesimal germ, and on this particle only. Exact, specific effect could go no further than this.

---

[*] Disulfo diphenyl disazo bi nitr n phenylene-diamine.

[†] Sodium salt of ditolyl bisazo bi amido naphthol disulphonic acid.

The latest of the dye-drugs is "flavine," also a discovery of Dr. Browning's. It is a yellow acridine, related to substances used in commerce for dyeing leather a brown color.** Flavine is known as the nearest approach to the "ideal antiseptic," because it destroys the germs of blood-poisoning in a wound without in any way interfering with the activity of the white warrior cells, which are the patient's own defense against the germs. The best of the old antiseptics are as destructive of white warrior cells as of germs, and the worst of them are much more destructive of warrior cells. Flavine, therefore, marks an important advance, and will soon be in universal use as an antiseptic.

For the moment the story ends here; but only for the moment. It is a safe assertion that many more of these specific drugs will be yielded by the coal-tar group, and that the demand for them will grow with experience of their uses. Already the scheme for combating venereal disease has established the use of salvarsan on what may be described as a national basis. From the commercial point of view this development is worthy of careful and earnest study. The scientist is to a great extent in the hands of the business man, since if further advances are to come, it is necessary that the pathologist should be brought into the closest touch with the technical chemist. It may be hoped that they will work together for the common good.

Picric Acid from Certain Gums.

It has long been known that the gum-resins, obtained from plants of the genus Xanthorrhoea and known commercially as acaroid, black-boy, botany-bay and grass-tree gums, yield picric acid upon treatment with nitric acid. This fact has not been utilized hitherto in a commercial way on account of the violence of the reaction, and the difficulty of controllng it, so as to secure a satisfactory output. Miller and Irlam (Br. Pat. 104,352, of 1916) have overcome this difficulty by treating the purified gum with limited amounts of acid, and in the cold, or at temperatures not exceeding 40° C. Not only picric acid, but also nitro-phenol and dinitrophenol are obtained by altering quantity and temperature.

DISINFECTANTS DERIVED FROM ACRIDINE DYESTUFFS

Dr. P. Hüssy and Dr. M. Hartmann, of Basel, Switzerland, have recently patented (Amer. Pat. 1,227,624, of May 29, 1917), processes for preparing a series of bactericidal derivatives from acridine dyestuffs, which are especially effective against streptococcus and splenitis bacilli.

The chief acridine dyes are phosphine, benzoflavine, acridine orange and acridine yellow. They are prepared from aniline, toluidine, dimethyl-aniline, etc. Theoretically, they are derivatives of the base acridine, $C_{13}H_9N$, which occurs in coal-tar.

The invention is described as follows:

"It is found, that valuable disinfectants of the acridine series are obtained, by acting with a soluble silver salt, on acridine dyestuffs, which may be alkylated at the acridine nitrogen, in presence of a convenient solvent, as for instance water or alcohol. The well defined crystalline compounds possess a prominent bactericidal action much superior to that of the heretofore known disinfectants with dyestuff character, as for instance the acridine dyestuffs employed as parent material, or certain derivatives of other basic dyestuffs, as for instance of methylene blue or rhodamine colors. Thus, for instance, the silver salts of the acridine derivatives, alkylated at the acridine nitrogen, act even in a state of the greatest dilution, (1:150000 to 1:180000), still growth checking, especially on streptococcus and splenitis bacilli, while the said alkylated acridine derivatives themselves show only a feeble development checking action already in dilution of 1:80000.

The toxicity of the new silver compounds is generally a trifling one and within the limits allowed for injection purposes.

For the preparation of the new compounds can be added, for instance, to a solution as concentrated as possible of the desired acridine dyestuffs, salt in a convenient solvent, as for instance, water or alcohol, a likewise concentrated solution of a silver salt soluble in the employed solvent, whereupon the crystallization of the silver compound formed begins mostly after a short time, and can be completed by refrigerating or, if desired, by adding a convenient precipitating agent, as for instance, ether. The separation of the new compounds is effected in the usual manner by filtration, washing and drying.

The new disinfectants constitute red or black powders, which dissolve in water with red to green coloration, in alcohol, acetic ether, glacial acetic acid and acetone with a strong fluorescence and in concentrated sulfuric acid with yellow to red colorations.

The process is illustrated by the following examples:

Example 1:—12.5 parts of the chemically pure nitrate of the acridine dyestuff, methylated at the

---

**Flavine is closely related to phosphine—a mixture of the salts of unsymetric diamido-phenyl-acridine with higher homologues.

acridine nitrogen, obtained in the known manner by heating 2:7-dimethyl-3:6-diamino-acridine with methyl chloride under pressure, are dissolved in as small a quantity as possible of boiling distilled water, and hereafter a solution of 7:8 parts silver nitrate, in a small quantity of water, is added to the solution. The new silver compound separates immediately, in the form of a crystalline tile-red precipitate; the separation is completed by cooling the mass or by allowing the same to stand for a certain time. Hereafter the precipitate is filtered off, washed first with a small quantity of ice water and afterward with alcohol and ether and dried *in vacuo*. The new silver compound constitutes in a dry state a brown-red powder, dissolving in water to red-orange solutions, in alcohol with orange-yellow coloration and strong fluorescence, in acetone, acetic ether and glacial acetic acid with yellow-green fluorescence and in concentrated sulfuric acid with yellow coloration. It is insoluble in ether.

Example 2:—20 parts 3:6-diamido-acridine, in form of the pure base, are suspended in a small quantity of hot water, and to the thus obtained suspension is added, while stirring, pure nitric acid, until the dyestuff is completely dissolved. Then a solution of 17 parts silver nitrate in 50 parts water is added, whereby the black-brown silver compound separates. After the mass has been allowed to stand for a certain time, the new silver compound is isolated by filtration, washed and dried *in vacuo*. It constitues a blue powder, which dissolves in water with green colorations and in alcohol, acetone and acetic ether with yellow-green fluorescence, and in glacial acetic acid with a brown-red coloration. It dissolves in concentrated sulfuric acid with wine-red coloration of strong fluorescence. It is insoluble in ether.

Interest Aroused in Suit Over "Aspirin" Trade-Mark

Manufacturers of drugs and medicines are watching with interest the progress of the suit brought by the Bayer Company, Inc., against the United Drug Company for alleged infringement of the trade-make "Aspirin." The plaintiffs contend that although the patent on the Hoffman process for the manufacture of acetyl salicylic acid expired in February of the present year, the trade-mark under which this drug has been advertised remained their exclusive property. The defendants hold that they are entitled to the use of the name "Aspirin," because it has "become generic within the principles laid down by the Supreme Court in the case of Singer Manufacturing Company v. June Manufacturing Company." Several concerns are now using the Hoffman process, but with the exception of four, including Lehn & Fink, New York, and the defendants, all are labeling their product "Acetyl Salicylic Acid." The suit is being tried in the United States District Court for the Southern District of New York.

EFFECT OF THE WAR ON THE PRODUCTION OF PHOTOGRAPHIC DEVELOPERS.

By T. THORNE BAKER.

Photographic developing agents presented a somewhat difficult problem soon after the outbreak of the war. The early ferrous oxalate developer, used when dry plates superseded the collodion processes, has the peculiar disadvantage that nearly half the speed of the plate is lost, which in these days of high-speed photographic work is, of course, a point of great importance. Nevertheless, a return to ferrous oxalate developers seemed almost necessary.

It so happened that practically all the modern organic developing agents—coal-tar derivatives—were manufactured in Germany. Many of them were the subjects of patents, and most of them could not be made on an economical basis outside of Germany. In the case of one in particular—hydroquinone—the Germans were able to sell this at a price so low that competition was almost out of the question, as the substance was produced in large quantities as a by-product in the manufacture of various coal-tar derivatives. In other cases, similar by-products or their derivatives, found to possess photographic reducing powers, were systematically "boomed" by means of trade literature until a market was established and so a channel secured for their outlet.

The use of hydroquinone, noted in 1880 by Sir William Abney, was followed in 1884 by hydroxylamine, and a year later by phenyl-hydrazine. In 1888 Andresen patented para-phenylenediamine. A year later, the naphthalene derivative known as eikonogen was discovered, and in 1891 the applicability of para-amidophenol, from which are derived many of the most important modern developers, particularly metol. This in 1914 was employed on an immense scale for cinematograph films and the development of X-ray plates.

Metol Substitutes.

Several substitutes for metol have since then been produced, for which various advantages have been claimed. In certain ways it is, perhaps, doubtful whether manufacturers have yet attained to the perfection of German-made metol, but the photographic properties of the substitutes are so satisfactory that no doubt need be entertained of our ability to compete in quality.

The high state of organization and the complete way in which nearly all coal-tar by-products are utilized enabled German aniline dye firms to produce these organic reducing agents at prices impossible in other countries in the present undeveloped state of the dye industry. Hence the cost of production of developing substances will depend to a large extent on the progress and expansion that take place in the manufacture of coal-tar derivatives. In the matter of the essential raw materials—benzene, phenol and naphthalene—we are, of course, happily placed. In our practical knowledge of the technical chemistry involved, we probably have much to learn.

To sum up the result as we find it today, it may be said that the large number of photographic developers in use two and a half years ago, each of which had its adherents, has diminished to two or three for the great bulk of photographic work—pyrogallol, hydroquinone, and the various metol "substitutes." These have been successfully manufactured by British and American chemists, and there is good reason to hope that the cost of their manufacture will be reduced.

MAY WAIVE PATENT LAW TO PROTECT GOVERNMENT FROM EXTORTION.

Steps to prevent the exaction of extortionate prices from the Government for drugs, medicines, remedies or devices required by the army or navy during war have been taken by Senator Atlee Pomerene, of Ohio, who has introduced into the Senate a bill (S. 2363) authorizing the Secretary of War and the Secretary of the Navy to manufacture such necessities regardless of whether they are already protected by patents or trade-marks. By this means the owners of these patents or trade-marks will be effectually prevented from taking advantage of the present urgent need by raising prices on Government contracts, although they will be allowed to have adequate compensations for the use of their formulas or manufacturing methods, and will also have the privilege of keeping the Government from using them in case the compensation is, in their opinion, inadequate.

USE OF COAL-TAR DYES AS MEDICINES.

Certain coal-tar dyes check the growth of tuberculosis germs, and, to a lesser degree, the growth of typhoid germs, according to a recent announcement of Dr. Paul A. Lewis, of the Henry Phipps Institute of the University of Pennsylvania, through the "Journal of Experimental Medicine." The azo compounds, because of their nitrogen contents, exhibit this beneficial property, while methylene blue dyes also display great potency in arresting the development of germ life. Experiments to determine the effects of dyes on pneumonia germs will be undertaken shortly.

The Cost of Salvarsan.

The rector of a German university recently stated that while the cost of manufacturing a kilogram of salvarsan did not exceed 8 marks, or nearly $2, the drug was sold at 16,000 marks ($3,808).

French Duty on Saccharin.

A French internal consumption duty of 200 francs per kilo has been imposed on saccharin and all artificial sweetening substances or chemical products assimilated thereto.

VII

MISCELLANEOUS

Nationality and Chemical Research

Dr. Alfred Rée, President of the British Society of Dyers and Colorists, in his presidential address at Manchester, on March 30, gave some interesting data on the rôle of nationality in the evolution of the coal-tar color industry. While the great bulk of the progress has taken place in Germany, it would appear that a large number of the most brilliant discoveries in this field, made in German laboratories, are due to the talent of chemists of French, Alsatian or Swiss origin, some even of Polish or Anglo-Saxon origin. Some of the most clever and expert German industrial chemists spent many years in England and benefited by a close study of English ways and methods before attempting to accomplish their great work in the land of their birth.

The past dominance of Germany, and also of Switzerland, in technical chemistry is due chiefly to the enormous number of chemists in the two countries. Relatively, in proportion to the population, Switzerland has fifty times as many well-trained chemists as are found in Great Britain, and Germany has forty times as many. Among such battalions, even armies, the chances of bringing to the forefront men of pronounced inventive ability are vastly heightened.

British Exports and Imports of Chemicals

The exports of chemicals, drugs, dyes and colors from Great Britain, for the month of March, 1917, showed a slight decrease, as compared with the corresponding period in 1915 and 1916. The figures are:

March, 1915	£1,997,635
" 1916	2,046,398
" 1917	1,960,799

The imports of chemicals and allied products, for the first three months of 1917, show a marked falling off as compared with 1916. The value was £5,796,584. In 1916 it was £7,302,648. The shrinkage in purchases of foreign dyes indicates that the British production of artificial colors is steadily gaining ground.

Oakes Co. to Erect New Buildings.

Work will shortly be begun on the new factory and office buildings which the Oakes Manufacturing Co., manufacturers of natural dyes, is to erect in Steinway Avenue, Long Island City. The factory will be a two-story structure, 60 x 100, and the office three stories, 32 x 100. The estimated cost is $60,000.

BOOK REVIEWS

THE ANILINE COLOR, DYESTUFF AND CHEMICAL CONDITIONS.

From August 1st, 1914, to April 1st, 1917. A Series of Addresses and Articles, Compiled by I. F. Stone. New York. 224 pp. Privately Printed.

To all who have been associated with the rapid development of the American coal-tar color industry, since the beginning of the present war, Mr. Stone's historic survey has been exceedingly welcome. This development has been so swift, so marvelous, so unprecedented in its nature, that the time had arrived when we needed to have the various stages of progress, and all the multiple factors presented in the proper light and well-co-ordinated.

No one is better fitted by broad and generous participation in the evolution of our new industry to portray the successive steps since August 1, 1914, than the author. His positions as vice-president of the Schoellkopf Aniline & Chemical Works of Buffalo, the leading American company engaged in the production of artificial colors, and likewise as president of the National Aniline & Chemical Co., of New York, a great distributing agency, have brought Mr. Stone closely into touch with all phases of the situation—technical problems and commercial actualities.

As he possesses a rare talent of clear, lucid exposition, Mr. Stone has been frequently called upon to portray existing conditions, as well as the possibilities and probabilities of the immediate future, before gatherings of chemists and textile associations, as well as in the technical press. These public addresses and published contributions, coming at intervals of a few months, constitute a genuine series of dissolving views, and present, in admirable perspective, the successive steps leading up to the present status of the nation's new industry.

Out of 20 such portrayals, some 13 have been selected, and arranged in chronological sequence they form the chief portion of the volume. They begin with an address before the "National Printing Ink Manufacturers' Credit Association," on September 25, 1914, and terminate with a convincing argument for the "Permanence of the American Dyestuff Industry," delivered before the Textile Club of New York, on March 3, 1917

In order to heighten the value of the compilation as a historic document and complete the survey of the general subject, the author has introduced a few studies by others prominently identified with the movement. Among these are the address by Mr. D. W. Jayne before the Society of Chemical Industry, in 1915, on "The Possibility of Establishing a Complete Dyestuff Industry in America;" Dr. B. C. Hesse's exhaustive tariff history of coal tar dyes, "Lest We Forget! Who Killed Cock Robin?" of August, 1915; Mr. J. F. Schoelkopf's admirable presentation of "The Aniline Industry from a Manufacturer's Viewpoint," October, 1915; Dr. W. Beckers' address before the Second National Silk Convention on "The Relationship of the Manufacture of Explosives to the Manufacture of Dyestuffs," November, 1916, and Dr. Thomas H. Norton's portrayal of "The Expansion of the American Dyestuff Industry," February, 1917.

Professor W. M. Gardner compiled, on a somewhat similar plan, in 1915, his interesting volume on "The British Coal-Tar Industry," which includes 33 articles, by prominent British Chemists, from 1868 to 1915, depicting every phase in the slow evolution of the industry in England.

Mr. Stone's work is much more dramatic, in bringing vividly before our eyes the quick sequence of accomplishment, as we have reached in less than 3 years, the stage of development attained, in nearly half a century, in the birth place of coal-tar color chemistry, by our transatlantic cousins.

The book offers many temptations for more or less ample quotation. Suffice it to reproduce from the closing address an outline of the general situation, as it was three months ago, and as it is now practically:

"Practically the only colors which are not now made in this country of any consequence are indigo and anthracene derivatives, known as vat colors, for the dyeing of ginghams, shirtings, etc. (although at this time there is one factory being erected for the manufacture of indigo); but it is possible to secure natural products like indigo, logwood, fustic, cutch, flavine, etc., which can be substituted until the artificial colors are either manufactured or again imported. And then alizarin colors, for which there is, as far as I know, no plan to manufacture, are easily replaced by the so-called chrome colors, which are practically as fast and available for men's wear, sweaters, heavy woolens, etc., in black, blue, brown, green, yellow and red. Therefore the shortage of these alizarins is really not so serious. There are some colors for lakes, called the para colors, which are not made here; but the lake manufacturers can easily get what they want by making their own lakes from paranitraniline and beta-naphthol, which are made here. A few other colors not made here are such specialties as rhodamine, auramine, patent blue, etc., but some are being brought over from Switzerland and England in fair quantities, so that they are obtainable, and can be used in connection with American colors for blending shades and making mixtures."

* * *

"The principal point, to continue the successful manufacture, is the question of the manufacture of the intermediates, on which they depend as their raw materials, and it is the intermediate manufacturers who will need the most help to maintain their position."

* * *

"There is some criticism as to the quality of the coal-tar products made in the United States since the war; but to this I can say that they are identically the same in every respect as the European products, as they are made from the same chemical formulae, and there is no reason, therefore, why they should not be fully as good in every way if they are properly manufactured, which they are by the competent factories. The trouble is that people in comparing colors do not compare the same colors, but take some color which is especially adapted for certain purposes, and compare it with colors which may be used for the purpose, but are not so well adapted, due usually to the ignorance of the people who use colors."

* * *

"To sum up what is now being manufactured, I would say that practically a full line of basic, acid, chrome and sulphur colors are being made. People in criticizing the development of the color manufacture should not forget that it would be impossible for us to do in two years, since the war, what it has taken Germany over fifty years to accomplish; in other words, make a complete line of colors for every purpose; but in making the staple colors such as we have been able to do and getting them to a point where we can supply the whole consumption of the country, I think we have accomplished wonders in the short period since the war, or a little over two years.

"The definite answer in connection with the manufacture of dyestuffs in America is therefore, as I have already stated, that the present conditions of the dyestuff supply are very satisfactory, and the future outlook is still more satisfactory in that we will make more colors, and everything indicates that the larger part of the business will remain in the hands of American manufacturers even after the war, instead of the European manufacturers who in former years have had a practical monopoly of this business."

With this hopeful and optimistic conclusion of Mr. Stone, "THE CHEMICAL ENGINEER" is in most hearty accord.

PROFITS OF SWISS COLOR MANUFACTURERS.

The Sandoz Chemical Works Co., one of the four large firms of Basel, Switzerland, engaged in the manufacture of coal-tar colors, declared a dividend of 25 per cent. on its business for 1916, and paid, in addition, a bonus of 100 per cent.

ANNUAL CHEMICAL DIRECTORY OF THE UNITED STATES.

Editor, B. F. Lovelace, Williams & Wilkins Company, Baltimore, 305 pp. Price $5.00.

American chemists will warmly welcome the appearance of this first issue of a handy work of reference, long needed by the profession. The field for such a directory has broadened immensely during the past three years. A multitude of chemical products are now currently manufactured in this country, for which we depended entirely upon foreign sources in 1914. The same is true of a great variety of technical and laboratory equipment, in constant requisition by the teaching, research, analytical or manufacturing chemist.

The editor of the "Annual Chemical Directory" has followed Charles Reade's advice—"Put yourself in his place," and has brought together in easy, compact form the answers to all the multiple inquiries of What? and Where? which have been constantly on the lips of chemists during the busy months since 1914.

Two-thirds of the book is devoted to the two lists of American manufacturers of chemicals and of apparatus and equipment. In each section there is a highly detailed, systematic classification. Manufacturers are enumerated alphabetically, under each heading, by states and their cities or towns. The first section, covering American chemicals, will be a revelation to any who have doubted the ability of the country's chemists to establish successfully in the United States the manufacture of a great variety of products, for which we have depended hitherto upon European sources. This is especially the case with coal-tar crudes, intermediates and finished dyes, medicinals, etc.

The concluding portion of the directory contains a number of convenient reference lists: Professional chemical firms, laboratories, federal, state, municipal and professional; colleges and universities offering chemical courses (both American and foreign); agricultural experiment stations (American and foreign); Federal and State officials charged with the examination of foods, drugs, etc.; technical and scientific societies (American and foreign); periodicals devoted to chemistry and allied branches (American and foreign); chemical works appearing in 1916; progress of chemistry in 1916; new devices and methods for handling industrial chemical problems.

In its fullness and careful classification this new directory compares favorably with the ponderous "Adressbuch" of the German chemical industry, which has hitherto been a model in this field.

The first issue of such a directory naturally exhibits various errors of omission and commission, which can be easily rectified in subsequent editions. The editor frankly recognizes his limitations and invites constructive criticism and suggestions.

Greater fullness can certainly be attained in connection with certain branches of chemical industry. Under "Sulphur Black" but a single firm is listed, out of a score now producing the important dyestuff. The existence of an American factory for manufacturing synthetic indigo is not indicated; the companies now producing potassium compounds along the Pacific coast and in Utah, as well as in connection with the cement industry, are not mentioned, etc., etc.

It would be eminently desirable to distinguish sharply between manufacturers and dealers, in connection with both chemicals and mechanical equipment.

In the lists of foreign universities, periodicals and publications, orthographic errors are numerous. A variety of abbreviations are employed in the list of periodicals, for which no explanations are appended. The value of this list would be notably lengthened if the various journals, instead of following a single alphabetical enumeration, were classified under separate headings, analytical chemistry, electrochemistry, pharmacy, etc.; and further by countries under each subheading.

The survey of chemical progress during 1916 is so suggestive and stimulating that it could well have been expanded beyond its modest limits.

A valuable feature in such a directory—possibly in the advertising pages—would be statements, not too brief, regarding the courses in leading American universities and schools of technology, open to students of chemistry and chemical engineering.

Another feature of great convenience would be a classified list of chemical patents issued during the year.

DYE NOTES

Cadmium Derivatives of Acridine Dyestuffs for Use as Bactericides.

Dr. Paul Hussy and Dr. Max Hartmann, of Basel, Switzerland, find that cadmium derivatives of various acridine colors possess as marked bactericidal properties, as the corresponding silver compounds. The method used for their preparation (Amer. Pat. 1,228,926, of June 5, 1917), is much similar to that employed in making the latter.

The various dyes of the acridine series or of their derivatives, obtained by alkylating the acridine nitrogen, are dissolved in either alcohol, pure water, or in water acidulated with hydrochloric acid. Concentrated solutions of cadmium chloride are added, and the new cadmium compounds crystalize out. They are of a reddish brownish color, and are soluble in water with reddish-brown or yellow, orange colorations, and in alcohol or sulfuric acid with green fluorescence.

Even when greatly diluted, these solutions act strongly upon bacteria, checking farther growth.

British Profits in the Artificial Color Industry.

Levinstein, Ltd., one of the leading British companies engaged in the manufacture of coal-tar colors, has declared an interim dividend of 15 per cent. on the account for 1917. For 1916, the dividend was 30 per cent.

To Manufacture Colors and Dyestuffs.

Zobel, Stern & Campbell, Inc., has been chartered to manufacture colors and dyestuffs, with a capital of $20,000, by H. E. Zobel, G. M. Campbell and B. F. Meyer, 253 Brooklyn, N. Y.

ULTRA VIOLET LIGHT

Its Application in Chemical Arts

By Carleton Ellis and A. A. Wells[*]

This Is the Fourth Installment of an Article Dealing with Investigations Conducted by the Writers Into the Possible Applications of Ultra Violet Light. The Present Installment Discusses the Work of Other Investigators in Connection with the Action of Its Rays on Organic Acids Containing Halogens and on Plants, Seeds, etc. The Physiological and Therapeutic Effects of the Light Are Also Discussed, Together with the Effects of Its Rays on the Eye. Part V Will Appear in the Next Issue.

PART IV.

Magnesium Sulphide.

All pure preparations of *magnesium sulphide* examined by *Tiede* (Ber. 49, 1745) when exposed for a few seconds to day or arc light became faintly luminous. The crude product was more faintly phosphorescent than the pure material. Magnesium sulphide is much more sensitive to long wave lengths. No excitation was observed with radium or Roentgen rays or in the light of the ultraviolet lamp. When exposed to direct cathode rays it shows lively blue or red fluorescence and a feeble afterglow.

Chlorine and Hydrogen.

The temperature coefficient of the photochemical action of monochromatic light on a mixture of *chlorine* and *hydrogen* has been investigated by *Padoa* and *Butironi* (Chem. Abs. 1356, 1917, Att. accad. Lincei. 24, II, 215-8 (1916). The results of experiments on the variability of the temperature coefficient of the reaction velocity of photochemical processes with changes in the wave length of the light used, have made desirable a similar study of simple photochemical reactions in which there can be no doubt that the reaction is purely photochemical. The reaction of hydrogen and chlorine in the presence of light fulfills these requirements. Favre and Silbermann (Ann. chim. phys. (3) 37, 297) found that different parts of the spectrum produced a catalysis of varying intensity. Bunsen and Roscoe found a miximum intensity of action between 413 and 395 uu. Bevan's experiments (Proc. Camb. Phil. Soc. 12, 398) showed that the temperature influences the velocity of this reaction and Kastle and Beatty (Am Chem J. 20, 159-63) found that at 120° the velocity of reaction is zero. Bunsen and Roscoe devised an actinometer for the study of this reaction, a modified form of which was used by Padoa. It was so constructed that the gas bulb could be kept in a thermostat with glass walls. The apparatus was mounted in a camera obscura and the source of light at once side was in a box provided with a hole, through which the beam to be studied was admitted to the bulb. Ultraviolet light was obtained from a mercury lamp. It was observed that the acceleration produced by increases of temperature is small for the ultraviolet light, is greater for violet and blue light and is maximum for green; for white light it is intermediate. The temperature coefficients when calculated bring this out still better, for white the coefficient is 1.29; for green (550-530) 1.50; for blue, (490-470) 1.31; for violet (460-440) 1.21; for ultraviolet (400-350) 1.17.

Organic Acids Containing Halogens.

The photochemical reactions between *bromacetic acid* and alcohol and between *chloracetic acid* and alcohol have been studied by *Cassel* (Z. physik. Chem. 92, 113-26 (1916)). The reactions were carried out in a transparent quartz vessel which was illuminated by an arc lamp of 1800 candle power. It has been found that decomposition into methyl alcohol, acetic aldehyde and the halogen acid occurs. The reaction is only sensitive to ultraviolet rays of a wave length of less than 250 uu. It has been observed that the bromine compound is more easily decomposed by alcohol both in the light and in the dark than the chlorine compound. In aqueous solution the halogen has been found to split off from 1-*bromosuccinic* acid more readily in the light than 1-*chlorosuccinic* acid in a corresponding solution.

Euler (Ber. 49, 1366-71 [1916]) has stated that when haloacetic acids in dilute water solution are exposed to the ultraviolet rays of a mercury lamp, halogen is split off at 18° with a velocity corresponding to that attained when the non-illuminated solutions are heated to about 100°. The light reaction differs from that in the dark in being of a lower order, increasingly smaller amounts of the halogen compounds decomposing per unit of time as the concentration increases. The reaction seemed to be well adapted to answering a question of importance from the photochemical standpoint, namely, whether illumination before the photochemical decomposition produces a loosening of the atomic unions in the molecule; specifically, whether a considerable part of the light-sensitive chloracetic acid possesses after the illumination an atomic grouping still corresponding to the usual formula for the acid but characterized by greater liability of reactivity in reaction in the dark. In flat quartz vessels 0.5 N solutions of dry chloracetic acid in benzene kept at 27° (under these conditions no measurable amount of chlorine is split off without illumination in the time intervals used) were exposed, at a distance of seven centimeters to the light of a Heraeus quartz mercury lamp; after 150 minutes five cubic centimeters of the solution were shaken with ten cubic centimeters of 0.5 N caustic soda, heated exactly thirty minutes at 70°, quickly cooled, freed from benzene, acidified with nitric acid, treated with silver nitrate at room temperature and the silver chloride determined in the usual way after standing a long time. Parallel determinations with unilluminated solutions were made simultaneously. The illuminated solutions gave 0.0328 grms. silver chloride, the non-illuminated one 0.0272 grms. That the excess in the first case (0.0022 grms. per hour illumination) was split off during the illumination, although the solvent was benzene was shown by precipitating the sliver chloride immediately after shaking the solution with caustic soda; the illuminated solution gave the same amount of silver chloride (0.0024 grms.) per hour, the non-illuminated one none; this, in conjunction with the first experiments also shows that the part of chloracetic acid undecomposed by illumination is decomposed by caustic soda with the same velocity as the non-illuminated chloracetic acid. To determine the nature of the decomposition produced by the light, large amounts of the illuminated solutions in benzene were shaken out with alkali, acidfied with sulphuric acid, freed from most of the chloracetic acid by steam distillation, extracted with ether, dried, evaporated and treated with chloroform to remove the rest of the chloracetic acid; the residue heated to 200-50° gave a sublimate of fumaric acid. The presence of an unsaturated acid was also detected by the behavior of the alkaline extract of the reaction solution towards dilute potassium permanganate, 3.5 cubic centimeters of a 0.01 N solution of which was decolorized by 5 cubic centimeters of a 0.5 N solution chloracetic acid in benzene, illuminated 4 hours. If the illuminated solution is shaken, with water (instead of caustic soda) until nearly all the acid is removed, then treated with chloroform and again shaken with water, the dried benzene-chloroform extract yields glycolide melting at 82°. Shaking the benzene with alkali also yields a small amount of polyglycolide. From the solubility relations of fumaric acid it appears that another unsaturated acid more soluble in benzene, ether, and chloroform is also formed. In ether instead of benzene the results are qualitatively the same but more chlorine split off (corresponding to 0.006 grms. silver chloride per hour illumination.) In water solution the difference between the decomposition velocity of the undissociated acid and the chloracetic acid is smaller in the light than in the dark. In benzene, bromacetic acid is decomposed more quickly than chloracetic acid contrary to what occurs in water solution in the light, but in agreement with the results obtained in the dark. (Chem. Abs., 1917-942).

Salts of Phthalic Acid.

In the course of some investigations on the salts of phthalic acid, which were carried out by *Ekely* and *Banta* (J. Amer. Chem. Soc., 1917, 762), lead phthalate was exposed in a small quartz crucible to the action of light from a quartz mercury vapor lamp. The outside layer of the salt decomposed rapidly with the formation of a yellowish brown substance of unknown composition, probably containing lead oxide. A similar experiment performed with *mercuric phthalate* showed the salt to be unaffected.

Sugar Synthesis.

Stoklasa notes that formic acid and not carbon dioxide and water was first produced by the action of ultraviolet rays on *formaldehyde* in the presence of caustic potash with access of air or oxygen. The formic acid was then decomposed into carbon dioxide and water. *Hexoses* (yielding a phenylosazone with m. p. 204-5°) were produced by the action of ultraviolet rays on carbon dioxide and caustic potash in the presence of ferrous compounds. No formaldehyde was formed from carbon dioxide (or acid potassium carbonate) and water under the influence of utraviolet rays. The carbohydrates produced during photosynthesis consisted of a mixture of hexoses (aldoses and ketoses) or their osazones. This synthetic sugar was not decomposed by Saccharomyces. Sugar synthesis can also proceed with the action of nascent hydrogen. A general survey of the literature is given by Stoklaša. (Zentr. Biochem. Biophys, 18, 370)

Cellulose.

It has been claimed by Witz that the action of light on *cellulose* produces oxycellulose, while Girard has asserted that the product is more probably hydrocellulose. To throw some light on this moot point *Dorée* and *Dyer* (J. Soc. Dyer's Colourists 33, 17-9, 1917; Chem. Abs., 1917, 1753) exposed some specially scoured and bleached cotton cloth to the rays of the Cooper-Hewitt mercury vapor lamp continuously for a period of one week and then tested the exposed cloth in various ways. The results of their experiments are tabulated and the conclusion is drawn that utraviolet light under the conditions employed converts cellulose with complete loss of tensile strength into an oxycellulose.

Flour.

Ultra violet radiation has been suggested in the treatment of flour with axidizing agents. The process of the *Naamlooze Vennootschap Industrielle Maatschappij Voorheen Noury and Van Der Lande* employs a peroxide (British Patent 102,967, Dec. 22, 1915; Chem. Abs., 1917, 1219). Flour or meal is mixed with a small quantity of an inorganic or organic peroxide and then subjected to a physical or chemical treatment to decompose the peroxide. In an example, bolted flour is mixed with 0.7% of a solution of hydrogen peroxide of 3% strength, and then passed in a layer 3 cm. thick on a belt conveyer, through a room in which mercury vapor lamps are situated.

Protein.

The action of ultraviolet rays on *egg* and *serum proteins* has been found by Schanz (Arch. ges. Physiol. 164, 445-56, 1916; Chem. Zentr. 1916, II, 670-1; Chem. Abs., 1916, 1656) to bring about a considerable degree of modification. In alkaline solution the amount of bodies precipitated by ammonium sulphate and sodium chloride was decreased, while in acid solution, the amount precipitated was increased. The change produced by light is stated to be regarded as a gelatinization of the proteins. This action is increased by the presence of oxygen.

Action of the Rays on Seeds and Plants.

De Wolf and *Fry* (British Patent 23,339, Oct. 15, 1913) propose the treating of *seeds,* by subjecting them before sowing, to the action of ultraviolet rays from a mercury vapor or other electric lamp, with or without previous treatment with water or a solution of sodium nitrate or other manure. The seeds are placed in a tank having a cover which rises towards the center, the lamp rests in an aperture. The seeds are stirred by means of rakes introduced through openings at the ends of the lid, which are covered by a dark cloth. The lamp may be immersed in the liquid such as a dilute nitric acid solution in which the seeds are placed.

Pouget (Comptes. rend., 1911, 1184) notes that after exposure to the action of ultra violet rays, green *vanilla pods* yielded a distinct odor of vanillin, while similar pods protected from the rays gave no odor. The odor was perceptible after 2 hours exposure at a temperature of 68° C., or after 6 hours at 37° C. The development of the odor was accelerated by first immersing the pods in a very dilute solution of manganous-chloride.

Pouget (Comptes. rend., 1910, 151, 355) exposed certain plants containing *coumarin,* to the ultraviolet rays emitted by a quartz mercury vapor lamp (using 4 amperes at 110 volts). After a few minutes the odor of coumarin became perceptible. Other plants containing a water soluble glucoside, such as the cherry laurel, also developed an odor after a few minutes exposure to the rays. It appears that the cell is killed, while the enzymes survive. The action of the rays on these plants resembles that of anaesthetics.

Colloidal solutions obtained by extracting the seeds of plantago psyllium L., with water have been examined by *Gutbier* and *Huber* (Kolloid. Z. 1916, 19, 90; J. Chem. Soc. II 556-7) with special reference to the phenomena of ageing and the effects produced by the addition of electrolytes and the action of ultraviolet light.

Chlorophyll.

In experiments to show the significance of the action of ultraviolet rays on the photochemical synthesis of carbohydrates in cells containing chlorophyll, *Stoklasa* (Strahlentherepie 6, 119-72, 1915, Zentr. Biochem. Biophys. 18, 370-1, 1915) observed that after irradiation the young leaves of etiolated seedling of Pismu, Zea mais, Avena and Hordeum showed a dark green coloration in two hours, while solor radiation caused a similar color only after six hours exposure. Longer exposure did not injure the cell plasma. The cells of flowers, as well as those of plants grown under glass, were, however, more sensitive toward ultraviolet rays than the cells of green leaves. Crude chlorophyll in alcoholic solution was not decomposed by the action of ultraviolet rays during an exposure period of 5-60 minutes.

THE PHYSIOLOGICAL AND THERAPEUTIC EFFECTS OF ULTRAVIOLET LIGHT.

For the sake of completeness, a few details of the application of ultra violet light to the human body for remedial purposes have been added to this article. The authors realize that they may be open to criticism for presenting this matter in the columns of a journal devoted to chemical engineering. Our only apology for the inclusion of this material is that usually the first inquiry made by those who are starting out to investigate ultraviolet light and study its chemical activities has related to the physiological effects of this form of energy. Many rumors are extant concerning the severe effects of ultraviolet light and the more timid investigator is likely to work under misapprehension regarding the action of these rays on the human body. Reasonable precaution should of course be taken, but it is not necessary to resort to some of the protective measures which have been recommended by those insufficiently familiar with the action of the ultraviolet light in this respect. The citation of the manner of treatment by physicians of a number of cases in which ultraviolet light has been employed gives an idea of the action of the light under various conditions and is therefore more satisfying than any general statement of the effects produced. From this standpoint the following matter is of value to the engineer or chemist beginning experiments with ultraviolet light and in this aspect should not be considered irrelevant.

A type of ultraviolet lamp suited for therapeutic uses together with its method of operation, also some of the results obtained are described by Bach (Ultraviolet Light, published by Paul B. Hoeber, N. Y., 1916).

According to Bach, Finsen attributed his success with light treatment of certain local affections to the ultraviolet side of the spectrum. But the arc light used by the latter contained but few ultraviolet rays, and consequently the duration of the treatment was very much prolonged, and small surfaces only could be treated at any one time. The therapeutic quartz lamp (introduced in 1907 by the Quartzlampen Gesellschaft of Hanau, Germany, now made in the United States by the Hanovia Chemical & Manufacturing Co., Newark, N. J.), was used at first almost exclusively in surgery and in skin diseases, that is, local affections in the manner employed by Finsen. Later, after improvements by Kromayer it became most useful in this field. However, only in the last few years have the ultraviolet rays been employed in general treatment. A few affections such as inflammations of the skin which occurred in a number of metal works were thought to be caused by ultraviolet rays and this belief served for some time to deter their application in a general way.

Rollier and others found that sun baths, especially at great altitudes, such as in the Alps, were beneficial in the treatment of diseases of the nature of tuberculosis (especially of the bones and the joints). These results were considered due to an abundance of ultraviolet rays in the sun's rays at these altitudes. As the ultraviolet rays of sunlight are largely absorbed in passage through the atmosphere, the value of ultraviolet rays in the sun bath treatment was long doubted. In fact, in 1903, Rieder made the assertion that the medium or red heat ray was the controlling factor in the beneficial effects of the sun bath. The quartz lamp has afforded a means of studying the effects of ultraviolet rays upon the human body in general treatment, with the result that a considerable amount of data has already accumulated on this subject.

Two types of lamp are used in the treatment of diseases, the so-called "sun lamp" for general application or for the treatment of large areas and the Kromayer apparatus for local applications. The "sun lamp" consists of a quartz burner from two and one-half to five inches in length, mounted in an aluminum reflector, which in some cases is fitted with a shutter by means of which the area of the surface to be exposed to the ultraviolet rays may be controlled. On either or both ends as the case may be, the burner is fitted with strips of metal which are spread out fan-like, to serve as heat conductors and thus to control the temperature of the lamp.

The burner and reflector are adjustably mounted either on a stand or rope support. A rheostat forms a part of the equipment. The burners are made for 90-120 volts and 200-240 volts direct current. In case alternating current only is available a current rectifier or a motor generator set may be used. A form of lamp used by physicians is shown in Fig. 1.

The Kromayer lamp consists of a quartz burner about one-fourth inch in diameter, bent in the shape of a U. About one-third of the U portion is bent at right angles to the main portion and when in operation is inverted, so that the arc is drawn in this portion of the tube. The burner is placed in a water-cooled casing, which has a quartz lens for the emission of the light. This equipment is mounted on a stand in a manner which admits of free adjustment. In some cases blue filters are used to cut out the long heat and the very short ultraviolet rays.

A modification of the "sun lamp" is equipped with a ring of incandescent lamps surrounding the reflector of the mercury vapor lamp. These radiate heat and tend to counteract the coldness experienced by some persons during treatment, especially when protracted. The effect of this form of treatment is more like a natural sun bath.

Bach recommends that the eyes should be protected by the use of goggles or of a dark cloth, as ultraviolet rays may cause a painful inflammation of the conjunctiva. The light which is reflected from bright surfaces after a long exposure may cause conjunctivitis or an uncomfortable irritation of the eyes.

It is claimed, however, that ultraviolet light is not permanently injurious to the eyes, even in the case of abuse, any inflammation of the conjunctiva that may occur healing in a few days without special treatment. Burning of the skin by the ultraviolet rays also is stated not to result in any lasting injury. Individuals vary considerably in their resistance to the effect of the rays and the ultraviolet light therefore should not be used indiscriminately.

When starting treatment with ultraviolet rays, there is a feeling of warmth, later a slight tingling is experienced and by strong radiation burning of the skin results. This effect usually disappears in two or three days. In one case reported to the authors, an irritation of the skin persisted for a long period after only a moderate exposure. There is no visible change during the treatment of dry lesions, but moist surfaces such as bleeding or secreting wounds begin to dry up after a few minutes exposure. Usually in two to four hours after a treatment, redness appears on the part which has been exposed. The erythema persists for two or three days and is followed by a tan. Moist surfaces which have been dried by the effect of the light remain dry. During the first "general" treatment, that is, exposure of large area, there is no visible change, or merely a slight reddening. In three or four hours if the radiation has been very strong, the exposed surface shows a decided redness, and blisters may develop. The redness decreases gradually and within two or three days some pigmentation appears. Owing to the darkening of the skin thus produced, subsequent treatments are not usually accompanied by further reddening or blistering of the skin but there is increased tanning. If, however, the intervals between treatments are unduly long, or the treatment is very severe, the effect may be the same as resulting from the first treatment.

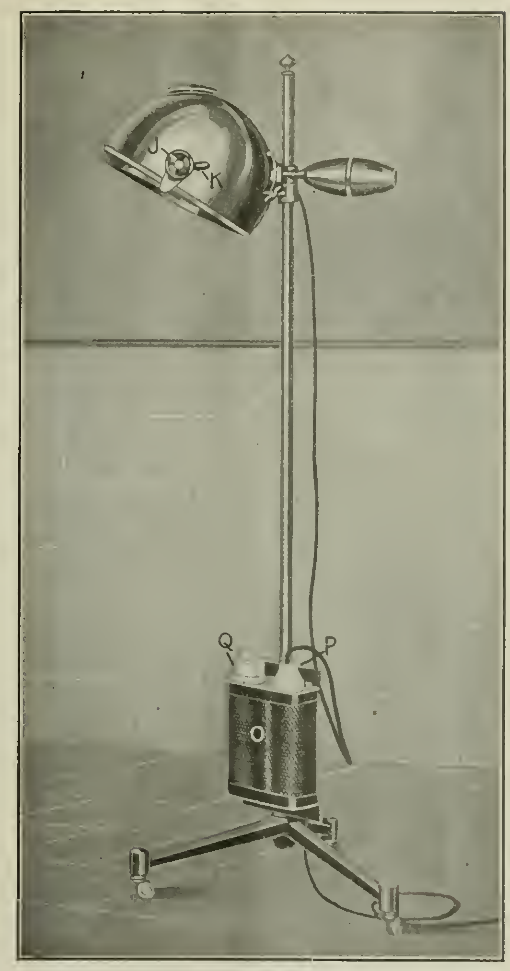

Figure 1. Type of Ultraviolet Lamp Used by Physicians.
(Courtesy Hanovia Chem. and Manf. Co.)

Injuries, even in the case of very strong exposure, are considered hardly possible, as ultraviolet rays do not penetrate more than one-fiftieth of an inch into the skin; merely penetrating into the uppermost layer of the epithelium. Blisters are stated to heal invariably without leaving scars.

To ascertain the effect upon the skin, eyes, and general condition, Bach resorted to a heroic test. He applied the ultraviolet light with great intensity upon his own person, without protecting his eyes. An exposure of thirty minutes was given at a distance of 16-20 inches from a 3,000 candle-power lamp. The head and body were treated alternately. After three minutes there was a sensation of warmth and after ten minutes a burning sensation at the place of exposure. An intense reddening appeared in two or three hours after the treatment. This coloration disappeared in three days There was no blistering, but the epidermis became dry and hard, and peeled off within a week, being replaced by a new epidermis which was elastic and brown. The conjunctiva commenced to redden in about two hours after the treatment, becoming inflamed and painful, but the inflammation disappeared in about three days without treatment. Immediately after the treatment and for days thereafter there was a feeling of freshness and of increased energy. This effect perhaps may be expressed as a case of over-stimulation of a person in good health.

A number of cases are reported by Bach, several of which are here noted to illustrate some of the classes of maladies treated by ultraviolet light.

In one case, a woman, forty-five years old, anaemic, with a thin, pale, and very sensitive skin, was treated on the back for three minutes at a distance of twenty inches from a 1,500 candle-power ultraviolet lamp. Two or three hours afterwards the whole body appeared red, including the unexposed parts. The reaction was so intense that the patient had to remain in bed. After three days the reddening, itching, and burning began to disappear, and although there was no blistering, the skin peeled off and was slightly browned. During this time there was a slight feeling of excitement, followed by a sensation of freshness, which lasted for days, after which the anaemia noticeably improved. This result shows that in cases of a sensitive skin, treatment should be commenced very gradually.

In another case, a man, thirty-five years old, who was inclined to congestion and headache, was given a treatment over head, breast, and abdomen for six minutes, at a distance of forty inches from a 3,000 candle-power ultraviolet light. After three minutes treatment, congestion in the head and ringing in the ears appeared, which disappeared on taking the patient into the open air. For two days after the treatment, he had headache, but afterwards felt better and fresher than before. Subsequent treatments given with the head covered were without ill effects and had a good effect upon the tendency to con-head and of headache, the head itself should not be ex-gestion. It is stated that in cases of congestion in the posed to the ultraviolet rays.

In another instance, a man, thirty-four years of age, who was in a state of advanced pulmonary tuberculosis, received regular treatments two or three times a week for one year. Exposures as great as thirty minutes at a distance of twelve to twenty inches from a 1,500 candle-power ultraviolet lamp were given. The treatments were often so severe that blisters were formed, the skin became very brown and peeled repeatedly. Since this treatment hemorrhages have ceased and general health has greatly improved.

A badly infected wound was treated by Bach daily for three days over a period of from five to ten minutes at a distance of sixteen inches from an ultraviolet lamp. The first treatment arrested the hemorrhage and the wound healed without further complications.

Schaer has successfully treated burns by a few exposures with the ultraviolet rays. Philip has observed that the use of the ultraviolet light alone causes a complete disappearance of eczema. Bach claims to be obtained permanent improvement in a considerable number of cases of heart trouble by treatment with the ultraviolet rays, but in order to accomplish this result he states the radiation employed was so severe as to produce hyperaemia of the skin with subsequent pigmentation. After each application the pulse became fuller and slower, and the breathing easier. In most cases the relief of the heart was noticeable even during the treatment and the patients themselves became conscious of improved respiration. Ostermann obtained excellent results with the ultraviolet lamp in the treatment of cases of hypersecretion and hyperacidity. Even very severe cases were benefited. After two or three treatments together with dietic measures, which alone had formerly been much less effective, unpleasant symptoms disappeared, the appetite improved and the weight increased. Siemon has reported (Munchener Medizinische Wochenschrift 48, 1914) on the use of quartz light in tetanus. Bach has cured a suppurating gunshot wound by three treatments with ultraviolet light, and numerous reports have been received from army surgeons telling of excellent results obtained in the treatment of wounds, and of nervous affections.

The successful use of the ultraviolet light in treating wounds, nervous affections, rheumatism, gout and anaemic conditions is of special interest at the present time because of the possibilities of application to good advantage in the care of wounded and sick soldiers.

At a private interview which one of the writers of this paper had with Dr. Donald McCaskey of 24 West 59th Street, New York, Dr. McCaskey stated that he is using ultraviolet light with marked success and he predicts that in the future its therapeutic uses will undoubtedly be still wider. Therapeutically, the use of ultraviolet rays is still in the experimental stage, and no fixed rules for its use, such as dosages to be given to certain patients are available. McCaskey states, however, that he hopes to be able to work out some method by which he may be able to tell by preliminary examination just how to treat a patient, that is, what the time of exposure should be and at what distance from the patient the light should be placed. Ultraviolet light he says is not a specific except perhaps in conditions due to infection or cases such as carbuncles or other types of pus formation, but the light is a very valuable adjunct when accompanied by internal chemical adjustment of the nitrogen balance.

A number of cases of various kinds have been treated successfully by McCaskey and a few of the typical ones are briefly described.

A severe case of lobar pneumonia in which both lobes of the left lung were practically filled, temperature 104, respiration 42, blood pressure 210. The patient was given a severe ultraviolet light treatment on chest and back. After twelve hours a change was noted, the blood pressure, respiration and temperature dropped, becoming quite normal after three days.

A case of chronic arthritis in which the patient had been able to move the elbow only slightly. After a few weeks of treatment with ultraviolet light in conjunction with internal nitrogen adjustment, the patient regained practically complete control of the affected parts.

In cases of boils, abcesses and even carbuncles three or four days serve to completely remove the pus, when healing is normal and rapid. McCaskey's method of treating these cases is as follows: The inflamed part is given a severe treatment, for example, by touching the affected region with the lamp container or attachment, and giving an exposure sufficient to just avoid causing a blister. The surrounding tissues are then given a slight treatment with the light. After the incision is made, the light is inserted in the wound and the latter given a thorough treatment. The spine is also given an exposure.

In prolonged treatments as in the case of malnutrition, McCaskey gives the first exposure for from three to five minutes at a distance of from eight to fourteen inches. No second treatment is given until the effects of the resulting ultraviolet light burn have disappeared and peeling of the skin is completed. After a complete new skin has formed, exposures of about ten minutes at a distance of about six inches are given.

McCaskey relates an interesting experience he had some time ago. He was holding a conversation with a man who was given to drunkenness. This man stated that he would give up drinking if McCaskey would give him a substitute. The patient's boast was promptly taken up. He was given a severe treatment with ultraviolet light on back and chest, producing blisters. The man was given an internal treatment to remove the poisons from his system and put to bed. For two or three days the severe burn and blisters kept his mind occupied so that liquor became a secondary thought. A general internal treatment together with applications of ultraviolet light were given to build up the system. The vitality gains were remarkable, and the appetite for drink disappeared.

In the treatment of the scalp, it has been McCaskey's experience that in case the root follicles are still living, hair can be restored, by giving rather intense exposures of the scalp to the ultraviolet rays. One instance was cited in which after several months treatment a normal growth has been obtained on a patient who had completely lost his hair. In this connection it was noted that the scalp does not become accustomed to the effect of the rays and that it is practically as easy to cause a burn after a prolonged period of treatment as at the first exposure. McCaskey states that this is not an especially popular remedy, inasmuch as the treatments must be severe to obtain results, and as stated above, the scalp does not become accustomed to the treatment.

It is quite commonly supposed that exposures to the ultraviolet rays cause permanent injury to the eyes unless properly protected. This is said to be a fallacy by McCaskey, who states that both he and his nurses work about the light, at times not even wearing goggles and that no injury has occurred. The conjunctiva is affected to a greater or lesser degree, depending upon the individual and upon the strength of the light, the length of exposure, etc., but on removal from the radiation the irritated conjunctiva soon becomes normal. By exposure, day after day, the eye becomes somewhat accustomed to the light and is not so readily affected as at first, the conjunctiva cells not having the power to fortify themselves against the action of the rays, similar to the protective effect resulting from tanning of the skin. McCaskey does not use eye shields with his patients, it being sufficient in most cases for the patient merely to close the eyes. In the case of specially light-sensitive persons it may be necessary for the patient to place the fingers over the eyes as further protection.

To summarize, therefore, ultraviolet ray treatments have been found beneficial in therapeutics, although the work is still in the experimental stage. The ultraviolet ray is not a specific except perhaps in the case of pus pockets, and local infections, and in a majority of cases the light should be used in conjunction with internal chemical adjustment. Ultraviolet rays do not cause permanent injury to the eye, but do temporarily irritate the conjunctiva if given too strong exposure.

Mueller (Loss of Hair, published 1915, William R. Jenkins Co., New York) states that the Finsen light has not been of much use in the treatment of affections of the skin, but that the Kromayer lamp may be used successfully in treating certain scalp diseases such as ring-worm and circular baldness; still better results have been obtained with Nadelschmidt's modification of the quartz lamp (the Alpine Sun Lamp) with which he has treated over two hundred cases for loss of hair caused by various scalp diseases. It is stated that out of these cases treated, five and one-half per cent. were failures and eighty-four per cent. yielded satisfactory results. It is noted by Mueller that treatment with ultraviolet light conduces to a more rapid restoration of hair which has been lost due to illness or severe nervous strain. It is also noted that in treating hair with ultraviolet light the new growth of blonde hair is usually of a lighter shade than the original growth, while in cases of dark hair, the new growth is usually somewhat darker.

After a treatment of the scalp with ultraviolet light, a swelling is produced which disappears after a few days, but the redness which develops remains for about two weeks and leaves a distinct pigmentation. In order to secure successful results in the treatment of hair with ultraviolet light, it is considered necessary to expose the parts treated to the direct rays from the lamp and at a comparatively short distance. Rays which have been reflected and direct rays projected from too great a distance have little or no effect in producing a cure for scalp ailments.

It should be noted in connection with the treatment of hair by ultraviolet light that all celluloid articles such as combs or pins which may be in the path of the rays, should be removed, as by long exposure these may take fire.

Action of Ultraviolet Light on the Eye.

In addition to the effects noted above concerning the action of ultraviolet light on the eye, the following observations have been included:

Birch-Hirschfeld and *Stimmel* (Arch. Ophth. Festscher. Sattler 90, 198, 1915; Zentr. Biochem. Biophys. 18, 510-1, 1916) state that ultraviolet rays play a considerable role in the production of scotoma due to dazzling light; this form of scotoma is caused by the chemical transformation of substances associated with the perception of light and soon disappears. The production of cataract is also discussed in this connection.

Corlo (Ann. oculist, 142, 41; Zentr. Biochem. Biophys. 17, 648, 1915) has observed an incipient cataract formation in the posterior cortical layers of a perfectly healthy man who had been exposed during a period of three years to the action of mercury vapor light which was extremely rich in ultraviolet rays.

The mode of action of ultraviolet radiation in injuring *living cells*, with special reference to those constituting the *eye* have been investigated by *Burge*. (Am. J. Physiol. 39, 335-44 1916.) The effect of ultraviolet radiation on *paromecia* and *egg white* is to cause coagulation. The effective region of the spectrum lies between 254 and 302 uu. The eyes of frogs and fish living in tap water were not noticeably injured by five to twelve hours exposure to ultraviolet radiation, while in solutions containing calcium chloride or having sodium silicate in the cells of the eyelids and of the cornea the effectiveness of ultraviolet radiation in producing eye trouble is increased. Abnormal amounts of calcium salts on the skin also increase the effectiveness of the short wave lengths in sunlight in producing sunburn.

Spuler discusses some of the conflicting views entertained regarding the action of ultraviolet light on the retina and other media of the eye. (Carlsruhe Scientific Society, Scientific American, Sept. 13, 1913.) The subject is treated more particularly with reference to the problem of illumination.

Miscellaneous Effects.

Delbet and *Beauvy* (Compt. rend., 159, 278-91) have made a comparative study of the action of ultraviolet rays on the hemolytic power and colloidal state of blood serum. After subjecting blood serum to the action of ultraviolet rays for twenty-three hours no changes were noticed after ultramicroscopic examinations. The hemolytic power of the serum was reduced one-half after being subjected for seventy-five minutes to the rays.

Torraca (Int. Monatsschr. Anata., 30, 297-325; Zentr. Biochem. Biophys., 16, 892) states that the long continued action of ultraviolet rays causes degeneration of the cutaneous epithelia. A remarkable cap-like arrangement of the pigment around the nucleus was observed.

Henri and *Moycho* (Comptes. rend., 158, 1509-11) have measured the action of monochromatic ultraviolet rays on tissue; and the radiant energy corresponding to that which causes sunstroke.

Berthelot claims to have reproduced artificially the processes of digestion by the action of the ultraviolet rays from a mercury vapor lamp on food substances contained in a quartz vessel. The processes were produced without the aid of the ferments which play so great a part in the natural organism.

(To be continued in the July issue.)

THIRD NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES.

The Third National Exposition of Chemical Industries, to be held at the Grand Central Palace, New York, during the week of September 24th this year, preparations for which are in active progress, will this year be larger and more interesting than its predecessors. The advisory committee in charge is composed of Chas. H. Herty, chairman; Raymond F. Bacon, Leo H. Baekeland, Henry B. Faber, Colin G. Fink, Bernhard C. Hesse, A. D. Little, R. P. Perry, Wm. Cooper Proctor, E. F. Roeber, G. W. Thompson, T. B. Wagner, Utley Wedge and M. C. Whitaker. The managers are Charles F. Roth and F. W. Payne. At the close of the past exposition much of the space available on two floors then used was reengaged by exhibitors for this coming exposition. The present time sees these floors completely taken and the greater part of the available space on the third floor engaged.

Interesting Processes to Be Shown in "Movies."

The Bureau of Commercial Economics at Washington is again preparing many of the motion picture films that will be shown at the Exposition, and many exhibitors have now in preparation pictures showing phases in their work in the manufacture of their products. These will all be of absorbing interest, particularly as many are of processes that have been photographed for the first time, and their first showings will be made at the exposition.

The program of speakers has not yet been announced, but we are informed that it will be composed of many of the nation's leaders of thought, and men who have come prominently to the fore in the nation's hour of need.

The exposition is using this year a very attractive poster stamp which was obtained by a competition of the students of poster designing at Cooper Union, New York.

CONTENTS, JUNE, 1917

Coal-Tar Chemistry 121
Edited by Thomas H. Norton, Ph.D., Sc.D.

Under which is included:

I—EDITORIALS:

Foreword 121
The Merger of Leading Manufacturers of Coal-Tar Crudes, Intermediates and Colors....... 121
America's Chemical Progress................ 126
George H. Bruce, A.M., LL.B.
Coal-Tar Chemists to Advise Government..... 126

II—COAL-TAR CRUDES:

Standardization of Benzol Tests in Coke Works. 127
Receivers of Aetna Explosives Co. Secure Privilege to Fulfill Contract................ 127
Explosion in Barrett Co. Plant.............. 127

III—COAL-TAR INTERMEDIATES:

A Cyclic Process for the Manufacture of Phenols 128
Electrolytic Production of Coal-Tar Intermediates 128
Manufacture of Sulfonic Acids.............. 129

IV—ARTIFICIAL COLORS:

Manufacture of Coal-Tar Colors in England:

I—Position on the Outbreak of War........ 129
C. M. Whittaker, B.Sc.
II—Progress in British Dye Making.... ... 130
Anonymous.
Growth of the Coal-Tar Color Industry in Other Lands 133
A New Method for the Use of Chrome Mordant. 135
Coal-Tar Research at Huddersfield.......... 135
War-Time Utilization of German Patents..... 135
American Synthetic Indigo.................. 135
Valuable Dye Discoveries Reported.......... 135

V—NATURAL DYES:

Present Position of Natural Dyes in British Industries 136
Natural Indigo 137
Says U. S. Army Heads Discriminate Against Vegetable Dyes 138

VI—SYNTHETIC DRUGS AND PERFUMES. PHOTOGRAPHIC DEVELOPERS:

Synthetic Perfumes 138
Ernest J. Parry, B.Sc., F.I.C.
Synthetic Drugs Obtained from Coal-Tar..... 139
Picric Acid from Certain Gums.............. 141
Disinfectants Derived from Acridine Dyestuffs. 141
Interest Aroused in Suit Over "Aspirin" as a Trade-Mark 142
Effect of the War on the Production of Photographic Developers 142
T. Thorne Baker.
May Waive Patent Law to Protect Government from Extortion 143
Coal-Tar Dyes as Medicines................. 143
Cost of Salvarsan.......................... 143
French Duty on Saccharin................... 143

VII—MISCELLANEOUS:

Nationality and Chemical Research.......... 143
British Exports and Imports of Chemicals.... 143
Oakes Co. to Erect New Buildings.......... 143

VIII—BOOK REVIEWS:

"The Aniline Color, Dyestuff and Chemical Conditions" 144
"Annual Chemical Directory of the United States" 145
Profits of Swiss Color Manufacturers......... 145

IX—WHOLESALE PRICES OF COAL-TAR PRODUCTS:

Crudes, Intermediates and Explosives, Synthetic Medicinals, Flavors and Perfumes, Photographic Developers, Artificial Colors........ 146
Natural Dyestuffs, Dyewoods and Raw Materials, Extracts, Dyeing Accessories......... 147

DYE NOTES:

Cadmium Derivatives of Acridine Dyestuffs for Use as Bactericides...................... 147
British Profits in the Artificial Color Industry.. 147
Zobel, Stern & Campbell Incorporated......... 147
Ultra-Violet Light: Its Application in Chemical Arts. Part IV.......................... 148
Carleton Ellis and A. A. Wells.
Table of Contents.......................... 154
Chemical Investigation, Efficiency and Control.... 155
Conducted by Charles B. Davis.
Distillates: News Notes of Chemical and Allied Industries 156
Foreign Trade Opportunities................. 158
June Prices of Chemicals.................... 160

POSITION WANTED: College trained chemist wishes position in dye, food, drug, or similar concern; steady and reliable; do not ask higher wages than I can earn.
ROBT G. EVANS, M. A., Jamestown, Pa.

CHEMICAL INVESTIGATION
EFFICIENCY & CONTROL

CONDUCTED BY CHARLES B. DAVIS, F.C.S.

ALL classes of work covered by the following subjects will be done for readers of "The Chemical Engineer" through this department by Mr. Davis: Special research of every description; analysis and reproduction of any commercial product; prevention of waste and utilization of by-products on the most economical basis; valuation of raw materials; food analysis, and disputed points in regard to adulteration, labeling, and the enforcement of pure food laws; bacteriological and enzymatic examinations, including fermentation tests, pure yeast cultures, beverages of all kinds; development of chemical inventions and industrial processes; examinations and advice on special machinery.

Inquiries of a minor character will be answered on this page, while major matters involving personal investigations, analyses, etc., will, if desired, be treated confidentially through the mails. All questions, materials for analysis, or letters leading to the opening of negotiations for special work will receive prompt attention if addressed to

CHARLES B. DAVIS,
Care of "The Chemical Engineer," 118 East 28th Street,
New York City.

J. A. K. If you will forward me exact data as to the construction of your machine and also where I may see it in operation, I will be pleased to submit it to some practical tests and render my report. The fee in a case of this sort cannot be determined until the tests have been made.

G. A. M. One cord of hard maple, weighing 3,875 lbs. will yield in good practice, 11.8 gallons of 82% wood alcohol and 293 lbs. of 80% acetate of lime. The yields for birch are not so high, while the alcohol yield for ash, tanbark, oak and eucalyptus is practically equal to maple.

J. E. S. The Bureau of Standards has discovered the secret (formerly held by the Germans) of making chemical procelain commercially, thus making the United States entirely independent of foreign markets. Without this product, the industrial chemists, pushed as they are now by war needs, would be seriously handicapped.

N. R. T. The patent on Aspirin (acetyl salicylic acid) has expired. The trade mark (being registered in the U. S. Patent Office) is still the exclusive property of the manufacturer. This product, having the formula $(C_6H_4. O. COCH_3. COOH.)$ is colorless, crystalline and melts at 135° C. It is soluble in alcohol and ether but only slightly so in water.

G. S. D. The Meat Inspection Laboratories specify in their regulations just what may be added to meats for curing, etc. Substances which impair wholesomeness are prohibited; only harmless artificial coloring is allowed and its presence must be declared on the label. Diseased and abnormal tissues are submitted to the Pathological Division. The samples containing parasites are studied by the Zoological Division.

A. E. M.—Arachis and Rape Oil is now being used as adulterants for Olive oil and should be looked for in all shipments. Half pint samples will be required for the analysis. The fee for this type of examination is moderate.

G. G. A. The coloring is entirely dependent on added turmeric, no anilin coloring being detectable. Turmeric, being an artificial dye, will necessarily have to be recorded on the label, in order to comply with the pure food law.

R. B. C.—You are correct in your statement that J. Bodnar, of Budapest, isolated the enzym, Zymose, from stored potatoes and ripe sugar beets, but in place of alcohol being formed, the soil bacteria enter as spores into the enzym extract thus converting the alcohol into acetic acid.

R. B. C.—The acetic acid content of your cider vinegar should be at least 4% and a pint sample will be required for the analysis. The volatile reducing substance present in the distillate is acetylmethylcarbinol $(CH_3. CHOH. CO. CH_3)$ and is a normal constituent of all cider vinegar.

H. E. W. You either do not maintain the proper pasteurizing temperature for the required period or your containers are not air tight. I would suggest that you send me a sample of both the treated and untreated material so that I may submit them to a very careful biological investigation. The bitterness of your milk and cream is caused by bacterial growth of very rare occurrence. I would advise the most scrupulous cleaning of all parts of your plant.

Charles B. Davis.

Those whose inquiries to this department have not as yet received attention must bear in mind that unless replies by mail are specifically requested, communications can only be considered in the order of their receipt.—Editor.

DISTILLATES

News Notes of Chemical and Allied Industries

Empire Gas Co.

The Empire Gas Co. has been incorporated with a capital of $500,000. A. J. Duncan, incorporator.

Paper and Paper Products.

Grass-Fiber Pulp & Paper Corporation, Dover, Del., has been incorporated with a capital of $150,000 to manufacture paper and paper products.

American Chemical Products Co.

American Chemical Products Co., Connellsville, Pa., has been incorporated with a capital of $6,000. The incorporators are N. J. Davidson, Connellsville; H. L. Mitchell, W. E. Moore, Pittsburgh.

Will Manufacture Kaolin.

Columbia Mineral Products Co., Columbia, S. C., has been incorporated with a capital of $20,000 to manufacture kaolin. The incorporators are F. L. Whittemore, F. W. Attwood, W. J. Keenan, Jr.

Good Chemical Co., Inc.

Good Chemical Co., Inc., Roanoke, Va., has been incorporated with a capital of $50,000 to conduct an oil business. The incorporators are L. M. Good, C. W. Robinson.

Central Glass Co.

Central Glass Co., Delaware, has been incorporated with a capital of $1,000,000 to manufacture glass of all kinds. The incorporators are C. M. Egner, L. Rimlinger.

Dyes, Chemicals, Colors and Drugs.

The Gold Leaf Natural Dye Co., Inc., New York, has been incorporated with a capital of $500,000 to deal in dyes, chemicals, colors and drugs. The incorporators are R. L. Warner, H. Campbell, 150 Nassau Street.

Chemicals, Dyestuffs, Colors, Etc.

Jaffrey Manufacturing Co., Trenton, N. J., has been incorporated with a capital of $50,000 to manufacture chemicals, dyestuffs, color, etc. The incorporators are B. D. Phillips, New York; H. H. Umberger, L. E. Conover, Trenton.

Lemaco Chemical Co.

The Lemaco Chemical Co., Hackensack, N. J., has been incorporated with a capital of $100,000 to manufacture chemicals, pharmaceutical chemicals and other preparations and articles. The incorporators are B. Barnet, Paterson; James H. McClellan, Boston, Mass.; I. Cohen, Ridgewood.

Will Manufacture Oxygen.

The Linde Air Products Co. will build a $100,000 factory to manufacture oxygen at Denver, Colorado.

Will Rebuild Fertilizer Plant.

The Arkansas Fertilizer Co., Little Rock, Arkansas, will rebuild, at a cost of about $25,000, its plant which was destroyed by fire some time ago.

Potash Company to Rebuild Plant.

The National Kelp Potash Company, Long Beach, Cal., will rebuild its plant which has been destroyed by fire.

Corcoran Chemical Co.

Corcoran Chemical Co., Durham, N. C., has been incorporated with a capital of $125,000 to carry on the business of chemists and druggists.

To Manufacture Chemicals.

L. J. Lewery & Co., Inc., New York City, has been incorporated with a capital of $25,000 to manufacture chemicals, etc. The incorporators are L. J. Lewery, W. Sutton, M. A. Kahl.

Colors, Chemicals, Etc.

Max Marx Color and Chemical Co., 192 Colt Street, Irvington, N. J., has been incorporated with a capital of $100,000 to manufacture chemicals, colors, etc.

Trinitrotoluol Now Duty Free.

The Giant Powder Company has been sustained by the Board of United States General Appraisers in its contention that T. N. T. should come into the country duty free.

New Silica Tube Mill Lining.

An adamant silica tube mill lining has recently been placed on the market by the Jasper Quarry Company, of Sioux City, Iowa. The new product has been successfully used in cyanide plants and cement mills and also in a silica plant.

Professor McCoy Resigns His Post.

Dr. H. N. McCoy, whose process of extracting radium from carnotite is being used by the Carnotite Production Co., of Chicago, and who is also interested in the production of thorium and related products, has resigned as professor in the chemistry department of the University of Chicago to devote his time to his technical interests. Dr. McCoy is a director in the Carnotite company and also in the Lindsay Light Company, also of Chicago.

Will Manufacture Acids.

Imperial Chemical Works, Warren, Pa., has been incorporated with a capital of $15,000 to manufacture acids. Clarence J. Hesen, incorporator.

By-Products from Waste Liquors.

The Wool-Wash Products Corporaton, Manhattan, has been incorporated with a capital stock of $5,000 by F. F. Pratt, E. Kemble and B. J. Crombie, 21 Park Row, New York City, to reclaim solids from waste wash liquors.

Dyes, Paints and Chemicals.

Durex Aniline Works, Inc., Manhattan, has been incorporated under the laws of New York to deal in dyes, paints and chemicals. The stock is $10,000, and the incorporators are S. E. Baer, H. M. and M. Toch, 329 West 86th Street, New York City.

Coal-Tar Products.

The Congoleum Company has been incorporated under the laws of Pennsylvania with a capital stock of $200,000, to deal in coal-tar products. The New York representative is H. E. Huelat, 230 Fifth Avenue. New York City.

Dixie Graphite Co.

Dixie Graphite Co., Delaware, has been incorporated with a capital of $150,000 to manufacture graphite, iron and steel. The incorporators are C. E. Brooks, Ashland, Ala.; W. L. Shumate, Jr., F. W. McMiller, J. F. Berry, Birmingham, Ala.

Chemicals, Drugs, Paints, Etc.

Eastern Aniline and Chemical Co., Inc., has been incorporated in Delaware with a capital of $2,500,000 to manufacture chemicals, drugs, paints, etc. The incorporators are C. L. Jordan, George F. Barght, G. G. Gates, Yonkers, N. Y.

Aniline Dyes.

24625.—A company in India wishes to be put in touch with American manufacturers and exporters of mill, gin, and railway stores, machinery, hardware, electric goods, aniline dyes, canvas and rubber goods, etc. Catalogues, quotations, etc., should be submitted. References.

Burrell to Direct Gas Warfare Investigation.

Research work on matters pertaining to gas warfare to be carried on by the U. S. Bureau of Mines, will be conducted under the direction of G. A. Burrell, consulting chemical engineer of Pittsburgh, Pa. Mr. Burrell has been in charge of the Bureau's gas investigations for the past eight years, and was appointed to this new task by Van H. Manning, director, who is chairman of a committee of the National Research Council, which is a branch of the Council of National Defence.

Chemicals.

Toronto Chemical Mfg. Company, New York, has been incorporated with a capital of $20,000 to manufacture chemicals. The incorporators are E. A. Eichner, J. M. Cuff, M. Mouilus, 220 West 42d street.

U. S. Gun Oil Co.

U. S. Gun Oil Company, Beaumont, Texas, has been incorporated with a capital of $20,000. The incorporators are E. T. Dickson, A. L. Dickinson, J. M. Johnson.

Southern Oxygen Co.

The Southern Oxygen Company, Austin, Texas, has been incorporated with a capital of $20,000. The incorporators are E. H. Perry, D. C. Reed, F. G. Smith, O. H. Miliken and J. B. Robertson.

To Make Wood Alcohol.

Pierce & Stevens, Inc., Buffalo, N. Y., have been incorporated with a capital of $10,000 to manufacture wood alcohol. E. B., G. E. and A. E. Stevens, Buffalo, are the incorporators.

Inks, Acids and Paper.

The U. S. Patent Ink Sales Corporation, Manhattan, has been incorporated under the laws of New York with a capital of $50,000 to deal in inks, acids and paper by S. Werner, J. Mann and C. E. Ackerman, 1562 Broadway.

Drugs; Chemicals; Dyestuffs.

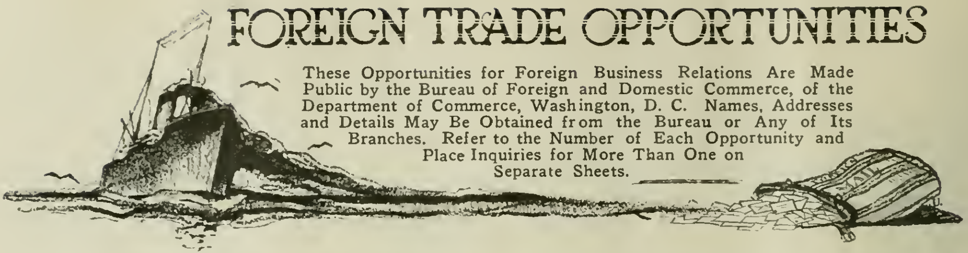
Jay White Manufacturing Co., Inc., Brooklyn, has been incorporated with a capital of $5,000 to manufacture drugs, chemicals and dyestuffs. M. Hillowitz, C. Jacobs and B. Rabinovitz, 396 Georgia Avenue, Brooklyn, are the incorporators.

Fifth Branch for Marden, Orth & Hastings.

Marden, Orth & Hastings Company, 61 Broadway, New York City, have opened a new branch in the Hoge building, Seattle, Washington, which makes the fifth American branch of this firm. The company handles heavy chemicals, coal-tar, intermediates, aniline dyes, dyewood extracts, tanning extracts, oils and greases.

Fertilizer Producers Meet.

Plans for the supply and distribution of fertilizers were discussed at a recent meeting in New York City of a sub-committee of the National Fertilizer Association, at which all of the producers present announced their willingness to place their plants at the disposal of the government. It was brought out at the meeting that steps were being taken to assure an adequate domestic supply of pyrites and sulphur, which were formerly imported in large quantities from abroad.



FOREIGN TRADE OPPORTUNITIES

These Opportunities for Foreign Business Relations Are Made Public by the Bureau of Foreign and Domestic Commerce, of the Department of Commerce, Washington, D. C. Names, Addresses and Details May Be Obtained from the Bureau or Any of Its Branches. Refer to the Number of Each Opportunity and Place Inquiries for More Than One on Separate Sheets.

Ethers for Temperance Drinks.

24547.—A man in Argentina wishes to represent American manufacturers and exporters of ethers used in the manufacture of soft or nonalcoholic drinks.

Glucose, Sugar, Vanillin.

24540.—An agency is desired by a firm in Switzerland for the sale of glucose, sugar, vanillin, tin boxes, vegetal and animal hair, cloth for mattresses, linen thread, snap buttons, raw cotton, oils and greases.

Leather.

24612.—A firm in Italy desires to purchase leather and any other articles, especially in leather dresser. Quotations should be made c. i. f. destination. Payment will be made by bank credit. Correspondence may be in English. References.

Coke Ovens, Chemical Plants.

24623.—An agency or representation of American firms is desired by a man in England for the sale of mining plants, colliery, coke ovens, by-products plants, chemical plants, or any other high-class engineering products. References.

Cerium Ore.

24564.—A merchant in Spain is in the market for cerium ore. Quotations should be made c. i. f. destination. Payment will be made upon delivery of goods. Articles should be packed as compact as possible. Correspondence should be in French or Spanish. Reference.

Explosives, Chemicals, Laboratory Apparatus.

24646.—The director of economic affairs of a foreign government is in the market for laboratory apparatus, photographic accessories and apparatus, bicycles and accessories, combustibles, waterworks, drains, electrical apparatus and supplies, clothes and dress goods, explosives, office stationery surgical instruments, agricultural materials and supplies, building materials, printers' supplies, medicines, furniture, tools, chemicals, food supplies, etc. A more complete list of the goods desired, and full information in regard to terms, etc., may be obtained from the bureau or its district office.

Acetyl Blue and Black Chrome Leather.

24677.—A company in Italy is in the market for acetyl blue and black chrome leather, 88 pounds of which can be used daily, if satisfactory. Quotations should be made c. i. f. destination. Correspondence should be in French or Italian. References.

Dyes and Chemicals.

24659.—The manager of a company in Japan, who is at present in the United States, wishes to be placed in communication with American manufacturers and exporters of general merchandise and all kinds of dyes and chemicals. Quotations should be made f. o. b. factory. Correspondence may be in English. Reference.

Scientific Instruments and Supplies.

24668.—A firm in Roumania wishes to be placed in communication with American manufacturers and exporters of precision instruments for physical appliances, optical instruments, general supplies for railroads, especially rolling stock, general supplies for the petroleum industry and viticulture, construction materials, and equipment for hospitals.

Drugs and Chemicals.

24653.—A man in India desires to purchase chemicals, drugs, patent medicines, mill, gin, and railway stores, patent foods for babies and invalids, condensed milk, oil engines, electrical goods and accessories, and machinery. He also wishes to entertain an agency proposition. Quotations should be made c. i. f. destination. Payment will be made by drafts through banks or through confirmed letter of credit. Correspondence may be in English. References.

Dyestuffs; Coal-Tar for Heating; Etc.

24655.—A commission merchant in France wishes to represent American manufacturers and exporters of different products, especially rare minerals and ores, particularly wolfram; silicates; bauxite; graphite; high petroleum oils, coal tar for industrial heating purposes; chemical products, especially dyestuffs, railway rails; fish plates and bolts; iron wire; automobile parts, platforms for railway freight cars and parts for freight cars, especially metal parts to be assembled in France.

Ferrocerium.

24562.—A firm in France is in the market for ferrocerium for cigar lighting.

Drugs and Chemicals.

24479.—Catalogues and prices are desired by a doctor in Central America from American manufacturers and exporters of drugs and chemicals. Correspondence should be in Spanish. Reference.

Saltpeter, Naphthalin and Other Chemicals.

25651.—A firm in Italy desires to purchase saltpeter, naphthalin, carbonate of ammonia, logwood and logwood extract, patinson magnesia, carbonate of magnesium, and crystallized soda. Quotations should be made c. i. f. destination. Correspondence should be in French or Italian. Reference.

Heavy Chemicals.

24692.—A commission merchant in Spain wishes to purchase and secure an agency for the sale of heavy chemicals. Quotations should be made f. o. b. New York. Payment will be made by cash against documents at destination. Correspondence may be in English. References.

Cheap Writing Paper and Pads.

23985.—A firm in Peru desires to purchase cheap ruled and unruled writing paper in packages, cheap envelopes, and cheap writing pads. Quotations should be made f. o. b. New York or c. i. f. Callao, if possible. Correspondence should be in Spanish. Reference.

Iron, Tin, Etc.

23941.—A man in Spain wishes to purchase iron, tin, and other metals. He also desires to entertain an agency proposition. Quotations should be made c. i. f. destination, if possible; otherwise f. o. b. New York. Payment will be made against shipping documents. Correspondence may be in English. Reference.

Alum, Chrome Alum and Acids.

24472.—A company in India wishes to be put in touch with American manufacturers and exporters of hardwood, piece goods, hosiery, oils, paints, drugs, belting, files, pulleys, mill machinery and parts, patent medicines, food for invalids, steel and iron plates, steel hoops, galvanized iron, wire netting, window glass, wire nails, cotton undershirts, towels, iron bars and angles, antimony, red lead, alum, chrome alum, acids, electrical goods, brass and copper wire, rods, pipes, paper washers, bolts, nuts, screws, cotton cords and ropes, dyed yarns, sanitary articles, such as bathtubs, urinals, etc.; heavy chemicals, such as zinc chloride, magnesium chloride, farina, calcium chloride, aniline dyes, rosin, etc. References.

Chemicals, Etc.

24575.—A firm in Spain desires to secure an agency for the sale of steel, hardware, chemicals, and kindred products. Reference.

Aniline Dyes.

24551.—A man in Argentina is desirous of representing American manufacturers and exporters of aniline dyes. Correspondence should be in Spanish or French. References.

Industrial Chemicals.

24514.—An agency is desired by a man in Italy for the sale of all kinds of merchandise, especially industrial chemicals, hardware, cutlery, greases, vegetable oils, etc. References.

Cellulose and Wood Pulp.

24675.—An agency is desired by a business man in Italy for the sale of cellulose and wood pulp for the manufacture of paper. Quotations should be made c. i. f. Correspondence should be in French or Italian. Reference.

Carbolic Acid.

24689.—A man in Spain wishes to secure an agency for the sale of carbolic acid. Quotations should be made f. o. b. New York. Payment will be made by cash against shipping documents at destination. Correspondence may be in English. References.

Chemicals: Tannin.

24589.—Quotations are desired by a man in France on steel plates for boilers and ships, angles, hoops, steel sheets, rounds, nails, iron and steel implements, lard, bacon, salmon, lobster, dry vegetables, leather, rubber, boots and shoes, oil and oil cakes, chemicals, hemp, jute, flax, colors, and tannin.

Sodium Bicarbonate.

24012—A merchant in China wishes to purchase bicarbonate of soda in 10-ton lots. The soda should be put up in double sacking. Quotations should be made c. i. f. Chinkiang. Cash will be paid. Correspondence may be in English, but Chinese is preferred.

Chemical Products and Aniline.

24672.—An agency is desired by a merchant in Argentina for the sale of supplies for druggists, liquor dealers, grocers, and dyers; chemical products and aniline, such as ethers, caramel, acetic acid, effervescent, orangeflower water, rose water, tartaric and citric acid; machines for making carbonated waters, soda, for bottling, putting on stoppers and caps, siphons and bottles for soda, and all machines connected with the liquor trade; and bottle caps. Correspondence should be in Spanish.

After the War—What of the Export Trade in Chemicals?

Chronological reference throughout the world, for generations to come, will center around the Titanic tragedy across the waters, steadily drawing into its crimson maelstrom one nation after another.

Events and epochs will be located as, "Before the World War"; "During the War"; or "After the War."

The chemists of this land, since August, 1914, have been forced to face a multitude of complex problems. Prior to that date, the United States depended almost exclusively upon European sources for the greater number of its manufactured chemicals, drugs and dyes. Suddenly the sources were closed to us. Nearly every branch of industrial activity was affected. Even the agriculturist was deprived of the wonted rations of potash for his broad acres. This country realized, as never before, to what a degree its industrial life depended upon the products of the technical chemist.

What was done? Did our manufacturers close their factories and abandon the struggle? Far from it!

Ingenious makeshifts were adopted here and there, but the great burden of responsibility was placed upon American chemists. They were put upon their mettle, and right nobly they responded.

We have a small army of American chemists. Some are occupied with the production of a few staple chemicals upon a large scale. Most are occupied normally with the control of the use of chemicals in hundreds of different branches. Suddenly they were summoned to create the manufacture of the most diverse compounds, with the production of which they were totally unfamiliar.

Yankee pluck, and determination, and adaptation and inventive ability were quite as marked assets in their inventory, as were technical and scientific attainments.

And the result? One by one the different phases of chemical manufacture, hitherto unknown to us, or known only in a tentative, hesitating way, have been organized and placed upon a permanent foundation. There remains still much to do. But never before, in the annals of technology, have so many new products been introduced into the cycle of a nation's industrial activity, in so short a space of time.

---

*Address, delivered by the Editor of the "Chemical Engineer," on June 30, 1917, at the Export Conference, held under the auspices of the first Eastern States Agricultural and Industrial Exposition, at Springfield, Mass.

The output of the new branches has been steadily increased, until in not a few cases, it exceeds the domestic consumptive demand.

Most marked has been the creation of a coal-tar chemical industry destined shortly to render us entirely independent of foreign sources for hundreds of synthetic colors, medicinals, flavors, perfumes and photographic chemicals.

We are creating a national potash industry, limited to a few compounds in point of number, but destined, ere long, to emancipate us from dependence upon the mines of Stassfurt.

We are likewise building up a national nitrogen industry, bound to free us soon, from paying further tribute to Chile.

The few chemical industries which we possessed before the war, have been expanded to a notable degree. Three years ago they attempted little beyond supplying the domestic demand. Now their products are sent in constantly increasing quantities to every part of the globe.

In the fiscal year 1913-14 the value of these exports was twenty-seven million dollars ($27,000,000). In the current fiscal year, 1916-17, the value will exceed one hundred and eighty million dollars ($180,000,000).

Three years ago our imports of chemicals were valued at ninety-four million dollars ($94,000,000). This year the value is about one hundred and seven million dollars ($107,000,000). The quantity is materially less than in 1913-14.

And now, our manufacturing chemists, our economists and our statesmen, are seeking to draw aside the veil of the future They ask: "After the war—what of this marvellous export trade in chemicals, increased sevenfold in the course of three years? Can we hold it to any extent? Or, will our present customers, upon the return of normal international excnanges, revert to the old-time sources of supply?"

No precise, categorical reply can be given to these inquiries. The factors involved are too numerous, and some are vague and uncertain.

A careful analysis of our present export trade in chemicals reveals, however, conditions and tendencies, which lead strongly to the conclusion that a goodly share of this phenomenal movement of one class of our products may be permanently retained, if the proper foresight, energy and resoluteness are displayed, and that without loss of time.

Some of our chemicals, especially the acids, are demanded in enormous quantities, for shipment to Europe, and are used almost exclusively in the manufacture of munitions of war. France, Italy and Great Britain are the chief purchasers. We have no reason to expect that this phase of the trade movement will continue after the war. Far different may be the case with our increased exports to other regions. The possibilities become evident if we establish a comparison between the quantities, or values, of various articles exported to continental divisions during the fiscal years 1912 and 1916:

*No detailed record was kept in 1912 of the exports of sodium compounds, as the quantities were insignificant. Even in 1915, the total value was less than one-quarter of the figure for 1916.

While figures for the fiscal year 1916-1917 are not yet available, it may be stated that the total exports of American chemicals are over twelve per cent. (12%) greater in value than was the case in 1915-16.

Unfortunately the statistical work of our Treasury Department is sadly restricted in regard to chemicals. Many would gladly know the details falling under the comprehensive designation above, of "miscellaneous chemicals," the total export value of which, for 1916, exceeded $56,000,000.

The survey of our shipments to continental divisions other than Europe, regions which have hitherto drawn their chemical supplies largely from Germany, and to a lesser extent from Great Britain, and a few adjacent countries, reveals at a glance how we have multiplied our economic relations with Latin America, Asia, Africa and Oceania. Numerous are the cases where the export has been trebled or quadrupled. Frequent are the instances where there is a tenfold increase. But when South America increases her purchases of white lead from sixty-two thousand (62,000) lbs. to three million four hundred and fifty-one thousand (3,451,000) lbs., or of dyestuffs from two thousand three hundred and ninety dollars ($2,390) to two hundred and sixty-five thousand dollars ($265,000), when Asia increases her import of miscellaneous chemicals from half a million dollars to nearly six million; or, when Oceania buys two million six hundred and forty-six thousand (2,646,000) lbs. of white lead from us, instead of five hundred and twenty-four thousand (524,000) lbs., we begin to realize the possibilities of our foreign trade in this field, which has hitherto been so neglected.

In 1906 the international trade in chemicals, drugs, dyes and fertilizers had a total value of five hundred and ninety-two million dollars ($592,000,000). At that time the purchases of non-European countries were:

Asia	$40,731,000.00
Africa	6,767,000 00
Oceania	2,322,000.00
Canada	10,933,000.00
Latin America	20,203,000.00
Total	$80,956,000.00

It is probable that the consumptive ability of these regions, under normal conditions, would be, today, nearly double the above figures, or about one hundred and fifty million dollars ($150,000,000).

Here is a territory in which American commercial enterprise is steadily gaining, in which we should intrench ourselves with a fixed determination to hold the situation.

If you ask just how this campaign is to be organized and how it is to be waged, I may not be able to outline with certainty every detailed feature. But I can tell you very easily, and with confident assurance, just how victory is *not* to be won.

It will most certainly not be gained if our American manufacturers of chemicals sit quietly and comfortably in their offices, patiently await the arrival of inquiries from the vast domain to the south of us, from Asia and Africa, and the islands of the sea, and placidly reply, in good Anglo-Saxon, to correspondence in a dozen different tongues, that their wares can be obtained in the quantities and containers customary to the domestic trade, against cash at time of shipment.

This is a time-honored procedure, but no branch of American export trade has ever achieved signal success by following the method.

A few weeks ago our nation was thrilled by the unexpected announcement that the commander-in-chief of the American expeditionary army had landed on the other side of the Atlantic, with his staff. And why the thrill? We each knew instantly and instinctively that a vast amount of preparatory work had been accomplished within a marvellously short period of time. We knew that, in its broader outlines a plan of operation had been decided upon, involving the co-operation and the co-ordinated effort of many thousands upon this side of the ocean. And finally, we knew that definite provision had been made for the exact performance of thousands of minor details, before General Pershing faced the billows of the Atlantic and their lurking, hidden dangers.

Our campaign to secure and maintain a market for American-made chemicals in two score countries, scattered over the face of the globe, must be undertaken in the same spirit.

We must know exactly what chemicals, and in what quantities, each of the foreign countries, coming into consideration, requires in normal times. It is necessary to ascertain the style and size of container to which the trade or the local consumer is accustomed, the general appearance of labels, the data required upon them, the varying degrees of purity or strength called for, legal requirements concerning the trade in chemicals and drugs, etc., etc.

Furthermore, we should know exactly the sources of the chemicals purchased before the war, the prices then paid, the system of credits and the whole mechanism of bringing the wares of foreign origin into the hands of the final consumer.

Concrete problems then assume shape. Given the current wholesale rate in Brazil, for, say, potassium permanganate in 1914, can an American producer furnish it at the same or a lower quotation? If not, what possibility is there of so shaping the costs of production in the American factory, so that a satisfactory rate can be established?

It may be assumed with tolerable certainty that by the time, when normal international exchanges are resumed, our banking and shipping facilities, in connection with nearly all foreign fields for commercial rivalry, outside of Europe and the Mediterranean litoral, will be such that we can meet competitors on practically even terms.

The chief problem in any specific case will concern the purity and availability of the raw material at the disposal of the American producer, and his ability to manufacture at a cost, not above that of his European competitor.

It has become an axiom in the evolution of American industries, that, given an equality of cost in primary materials, despite our high wage rates, we can eventually bring the costs of production to, at least, a parity with those in other countries, once a branch of manufacture is thoroughly rooted here, established on a generous scale, and completely standardized. The steel trade, the manufacture of locomotives, of machine tools, of typewriters, of agricultural implements, and scores of other instances may be cited in support of the thesis.

Such must inevitably be the outcome in our chemical industry. One after another, new features are being introduced. Each expands until it is able to cover the domestic demand. It is standardized and the costs of production are brought down to the lowest possible figure, in order to preclude competition at home. Now comes the question—to what extent can an output be found outside of our own territories?

This query cannot be answered exactly and intelligently, until the various categories of data, enumerated above, and applicable to the special product in question, have been ascertained.

Once in possession of the facts, however, the way is clear to plan for an aggressive campaign. The American producer faces, at this stage, the all-important problem—to what extent is he warranted by the consumption of his wares in any given country, in making the direct attempt to establish business connections?

In the great majority of cases he is sure to decide that the prospective gain is not sufficient to overbalance the outlay incident to securing a safe market for his specialties at most foreign distributing points. In the aggregate, the demand for his products may be large. The actual consumption in the individual countries will be, in most cases, too small to warrant separate, aggressive, energetic efforts to secure a firm foothold and meet eventual competition.

The problem is qute different from that encountered by the men who have built up our foreign trade in petroleum or cottonseed products, in locomotives, machine tools and the like. It is an attempt to displace the staple wares, supplied, until recently by the nation most powerful in its chemical industry and in the selling of its wares.

We can make the attempt, and with a fair chance of success. There is, however, but one general method of procedure which offers a confident assurance of achieving that success.

The simple Latin motto on our national coat of arms must be made the fundamental principle of our chemical industry, in a very literal and comprehensive manner, as far as its foreign relations are concerned, if permanent, durable results are to be assured.

The same unity of direction and control of details which characterize our expedition to the battlefields of France, must be duplicated in its broader aspects. The collective chemical industry must adopt the same policy and highly perfected mechanism, which has enabled our petroleum interests to establish permanent markets in practically every land.

What this prospective campaign demands is a carefully perfected organization, having for its sole object the building up of our chemical trade throughout the world.

It may result from the coming together, on a co-operative basis, of the chief representatives of the industry, or it may be established by far-sighted commercial or transportation interests, keenly alive to the possibilities of the immediate future.

Such a corporation would represent for the combined effort of all chemical branches in foreign territory the dominant, irrepressible tendency of the day, as we see it manifested in a single field, in the recent merger of the leading factors of the swiftly expanding coal-tar chemical industry of this country. To meet successfully the coming struggle of German rivals seeking to recover the lost dyestuff market, unity and solidarity are absolutely necessary. A solid front must be presented to the East.

In essentially the same spirit, a single corporate body could handle intelligently, effectively and comprehensively the foreign expansion of the entire chemical industry. It could collect the requisite data from each country. It could secure, on the most advantageous terms, the active co-operation, as agents, of the highly experienced and reliable wholesale firms in the chemical trade, in each leading center of distribution. It could gradually locate in such agencies, live, progressive American representatives, competent to infuse the national spirit and energy in the building up of the new relations.

The establishment of credits and banking connections could proceed hand in hand with the creation of chains of branches of American banking houses, soon to take place.

The organization of such a network of agencies, covering practically the globe, would involve no more labor or outlay for the entire industry, than it would for a single enterprising manufacturer, ambitious to create widespread foreign outlets for one or more of his specialized products.

The central corporation could not only secure notable economies by this system of collective representation, it could likewise reduce the item of transportation to the lowest possible figure, by its extensive annual contracts.

Its great function would be to make firm contracts for annual supplies in all distributing foreign centers, total the amounts, and make equally firm annual contracts with domestic producers to cover the needed quantities. The financing of such a corporation should be on such a scale that domestic producers would receive cash payment on the arrival of wares at the American port of shipment. Such a method of procedure would enable the American manufacturer of chemicals to quote figures for his annual shipments to foreign markets, with the lowest possible margin of profit. He would be entirely free from any uncertainty or risk, and could plan definitely for his monthly output, above the demands of the domestic consumption of his special wares.

In principle the mechanism of such a corporation would not be essentially different from that of our great steel corporation. In the latter the closest possible relation is established between iron mines, blast furnaces, steel and rolling mills, and the final consumers of the varied products, all through the medium of the single, central organization. The economies and advantages resultant from such combination and consolidation are evident to every business man.

It is only by the economies due to such a similar concentration in the merchandizing abroad of our chemicals and dyes and drugs that we can meet the rivalry of European competitors.

For a certain number of years we shall possess an artificial advantage. As a rule, business and sentiment have little to do with each other. But we all know that the passions and bitterness evoked by the great conflict now raging will affect commercial relations for years to come. Russia, France, Great Britain and her colonies and the remainder of their allies, or of those in close sympathy with their aims, will for a long time purchase by preference in the American market.

I have passed in rapid review the salient features of the situation and its wonderful possibilities. I am firmly convinced that we have it in our power to bring about a notable achievement in the expansion of our foreign trade, in establishing upon a permanent basis the demand throughout the world for the products of a comprehensive American chemical industry.

No other country possesses in equal wealth and variety the requisite raw materials. No country is better accustomed to finance and urge through to success projects of equal size and complexity. To no land is the major part of the world now looking with greater respect, admiration and confidence.

It remains for us to plan and carry into effect that combination, co-operation, consolidation and concentration of skilled and specialized effort, without which the attempt is useless. Above all, the golden opportunities of these fast-fleeting months should be utilized without delay! T. H. N.

The Necessity for an Early Standardization of Color Concentrations and Values

By H. Gardner McKerrow.

Something over a year ago it was a widely discussed question as to whether this country could make aniline dyestuffs which would fill the void left by the cessation of importations from Germany. Today this is no longer open to discussion. The work of twelve months has shown that colors in every way comparable with the best imported qualities can be, and are being, made in quantities which have already relieved the color using industries of this country from any fear of a ruinous shortage, or even of a partial dislocation of style requirements.

It is a matter of frequent remark that never were colors more brilliant than they are in the current styles, and when it is borne in mind that except for such left over stocks as were in the hands of certain dealers and mills, there has been practically no supply of imported colors available for nearly three years past, it becomes evident that the industry has passed the experimental stage and has reached a development of mature capability. With the exception of the comparatively limited supply from Switzerland, and the two lots which arrived by submarine—the extent and usefulness of which are even yet more or less mythical—there has been no importation of European dyes in that time, and it is fair to assume that American dyes are responsible for the vividness of the fashion shades now to be seen in the season's styles.

There is indeed, no reason why this should not be so; a chemical formula is a fixed factor, and given the possession of intermediates of a proper character and quality, the production of colors is a matter of chemical routine.

Now arrives the time, however, when American manufacturers must complete their intrenchments and protect their lines of communication, and so coordinate the various branches of their new industry that, when the world returns to sanity, they shall not be deprived piecemeal of the results of the magnificent effort which has been made.

No more important aspect of the question presents itself in this connection than that of "standardizing" the colors which are being manufactured by the forty or fifty establishments which have undertaken the development of the industry.

At present there are as many qualities of sulphur black or any other extensively used color as there are concerns making it. One firm makes what is termed a 5% color, while another makes a 7% or 8% quality.

But against what standard are these percentages estimated? Each chemist has his own standard, and when the matter is investigated it is generally disclosed that he has in his laboratory a standard which he has used for some years and which came originally from some supply which was available before the war, and which probably originated with some German dyestuff house at that time.

American Producers Must Have Own Standards.

American manufacturers, in order to hold the industry intact against future attack, must create their own standards, and there should be one table of such standards under which all can work, and against which all American made dyes can be offered. Every buyer of domestic dyes should be in a position to know that when he buys a color of a given strength or concentration it is sold to him under a guarantee that the strength or concentration is stated in terms of a well recognized standard, and that the value of it is in direct ratio with this standard.

No time should be lost in arranging for a conference of the leading makers of dyes at which this scale of standards would be fixed, and an adherence to such authoritative standards be secured for the protection of the industry.

Probably the best and fairest method of merchandising colors would be to offer them for sale at values per unit of coloring matter. On that basis all percentages and strengths, and all questions as to whether the colors were sold in paste or in powder form would be automatically adjusted.

Every manufacturer would be working on the same basis, and every purchaser of dyes would know at once the value of the color offered in relation to its price.

Standards Could Be Fixed by Permanent Board.

The ultimate outcome of such a conference would logically be in the establishment of a permanent board composed of recognized color chemists and manufacturers to which the whole trade would accord allegiance, and which would standardize the new colors as they were produced.

Such a board might very properly add to its functions the very important one of the arbitration of all disputes which might arise between manufacturers and purchasers on questions of strength and color value, eliminating litigation and saving the time which is now lost in such disputes, avoiding endless expense as well as the congestion of court dockets with which all industrial centers are now burdened.

A still further field of activity for such a permanent board would be logically available in connection with a phase of the industry which, while not of immediate urgency, is undoubtedly going to be one of the most important questions of the trade when the war is over—the arbitration of contract repudiations where this is based on questions of quality and the co-relation of deliveries with type samples.

In the early days of an impending shortage in supplies of dyestuffs, when the alarmist reports of the daily press induced scores of textile and paper mills to believe they were confronted with the necessity of shutting down their plants, contracts were eagerly entered into with the dyestuffs manufacturers who were in a position to offer goods, at prices and under conditions which were far more stringent than anything which had been experienced by American manufacturers prior to that time.

Prices at anywhere from five hundred to a thousand or more per cent. higher than normal were readily accepted, and stipulations as to delivery agreed upon which fully justified the description of the twelve months from October, 1915, to October, 1916, as a "seller's market."

Additional Work for Board.

So far, actuated partly without doubt by a patriotic desire to give support to the development of the new industry, but also by the absence of any degree of selection of strongly competitive conditions, mills have lived up to their contract undertakings with a fair measure of faithfulness. What the situation will be as the industry grows, and as competition in it increases, resulting in improved and reduced costs of manufacture and lower prices, and as the cost of intermediates becomes less, is another question.

Human nature would cease to express one of its most universal characteristics if, when that time arrives, there were not numerous attempts to repudiate the validity of what had come to be burdensome and unprofitable contracts. The most commonly employed method of accomplishing this would be to question the quality of the goods delivered, and to claim that these were not up to standard, and not equal to previous deliveries.

When that time arrives, what better assurance could those manufacturers who have invested millions of dollars in intermediate and dyestuff plants have that their interests could be protected, than the existence of a representative and expert board to which, by the mutual consent of the parties in interest, all questions of quality and standard could be referred with the knowledge that a decision would be rendered on an impartial finding as to facts, and with a minimum expenditure of time and money.

Such a board would necessarily have at its command a sufficiently equipped testing laboratory and a staff of experienced chemists, which laboratory could be made practically self-supporting out of the fees received from arbitrated cases, and from expert research work which it would be called upon to do.

Now is unquestionably the time to organize the machinery for some such development while the industry is still in its infancy, and while requirements are still such that a properly conceived mechanism of this nature could be established which would automatically adjust itself to future conditions, no matter to what proportions the industry may grow.

Eastern States Exposition

The first agricultural and industrial exposition of the New England States was held at Springfield, Mass., on June 23-30. The undertaking was admirably organized and brought together a stately number of exhibits of the leading industries of New England. They were handsomely housed in the spacious, permanent structures, erected in 1915, at Springfield, to serve for such purposes. Noteworthy, in this connection, were the instructive exhibits of the various bureaus of the Department of Commerce, which takes an increasingly active part in all such gatherings, tending to stimulate the expansion of the country's manufacturers and trade. The leading addresses on the opening day of the exposition were delivered by Governor Samuel F. McCall of Massachusetts, and by the Hon. Edwin F. Sweet, Assistant Secretary of Commerce, the latter choosing for his topic, "After the War—What?"

The most notable feature of the exposition was the series of export conferences, held daily. Under the management of Mr. Archibald J. Wolfe a large number of representatives of our exporting industries were gathered to discuss themes closely connected with the problems to be faced at the conclusion of the great war. The whole subject of the possibilities of mightily expanding our export trade and holding it in the face of intensive European competition was exhaustively studied from every point of view.

The leading address on "Textile Day" was by Mr. H. Gardner McKerrow, manager of the Textile Department of Marden, Orth & Hastings, New York, and an associate editor of the Chemical Engineer. It was devoted to "The New Dyestuff Industry." Some of the points of this address, elaborated in a more complete form, are to be found in the editorial columns of this issue.

The opening address on "Chemical Day" was by the editor of the *Chemical Engineer,* and is also reproduced in this number. It was devoted to the problems connected with the healthful expansion of the export trade in American chemicals.

He was followed by Mr. Louis K. Liggett, president of the United Drug Company of Boston, who discussed "Drug Exports After the War." Among other things he stated: "Since the outbreak of the war it is a question of either using the chemical industry of this country to supply our needs or ceasing to exist. For 25 years the chemical industry has been dependent upon coal-tar derivatives, and this will be true of the future. These coal derivatives we were importing and not producing. Today we have coal distilling and rectifying plants all over the country from which we are obtaining coal tar, benzol, toluol, etc., not only in sufficient quantities to supply our own needs, but actually adequate to take care of other parts of the world. Not less than $100,000,000 has been expended by us to bring about the development of this one product.

"Our exports following this war will depend upon two very important factors. The first factor will be the price of labor. If our labor prices are to be higher than those of European countries we are very apt to lose a large percentage of the export business that we have gained by reason of war conditions. As to whether our labor prices are to be higher is any man's guess. I have discussed this subject with many manufacturers who have had more experience than I with conditions in Europe. You can get as many different opinions as you will find different men on this subject. I personally am of the opinion that labor will have to be lower, following the war. I haven't the time to go into the reasons for it. I simply express it as my opinion, backed by the records of labor prices following all previous large wars.

"As to whether our labor prices will drop in comparison to the drop that will take place that will be determined only by the extent to which we will be involved in this war before it ends.

"The second factor in our ability to hold and increase our export business following the war is that of service. We have not learned yet that the foreign buying countries want their merchandise their way—not the American way; we have not learned that we must not ship our merchandise across the Equator in the same kind of containers that we ship across the Rockies; we have not learned yet that our customers' ideas should be ours, particularly when it is a foreign customer. Strange as it may seem, South American, and particularly the Latin speaking districts of Europe, do not consider price so much of a factor as they do service."

The closing address was by Mr. Albert H. Higbie of Madero Bros., New York, who spoke on "The Past, Present and Future of American Chemical Production and Export."

Mr. Higbie claimed that America, while not directly concerned in the struggle for democracy at the outbreak of the war in 1914, "lost its nerves" with the other neutrals. The sound financial structure of the country saved it from what might have been a disastrous panic. Enormous questions arose requiring immediate answers and attention—questions of vital importance to all branches of manufacture in this country. As a nation, we have a peculiar trait. We do not sit down in a laboratory and study for years, until we are forced to action. But when we are forced, we put our heart and soul into the work and are usually able to "put it over."

The Merger of Leading American Manufacturers of Coal-Tar Crudes, Intermediates and Colors

In the June issue of the Chemical Engineer, p. 122, a full account was given of the recent merger of the leading factors in the American coal-tar chemical industry leading to the incorporation of the "National Aniline and Chemical Co., Inc."

On June 21 the organization of the company was completed by the election of the following officers and directors: Wm. H. Nichols, chairman of the board; J. F. Schoellkopf, president; W. Beckers, first vice-president; I. F. Stone, second vice-president and treasurer; C. P. Hugo Schoellkopf, third vice-president; Wm. T. Miller, secretary.

The directors of the company are as follows: J. F. Schoellkopf, J. F. Shoellkopf, Jr., C. P. Hugo Schoellkopt, of the Schoellkopf Aniline and Chemical Works, Inc.; W. Beckers, Eugene Meyer, Jr., Chas. J. Thurnauer, of the W. Beckers Aniline and Chemical Works, Inc.; I. F. Stone, of the National Aniline and Chemical Company; Wm. H. Nichols, of the General Chemical Company; Henry Wigglesworth, J. M. Goetchius, of the General Chemical Company and Benzol Products Company; T. M. Rianhard, W. H. McIlravy, of the Barrett Company and Benzol Products Company; H. H. S. Handy, E. L. Pierce, of the Semet-Solvay Company and Benzol Products Company.

Financial Status.

The complete capitalization of the new company will include approximately 200,000 shares of 7 per cent. preferred stock of $100 par value, and 350,000 shares of common stock without par value. There are no bonds outstanding nor any other indebtedness except current liabilities. No public offering of the stocks of the company is contemplated, the total issue having been taken by the constituent companies in exchange for their properties.

The productive capacity of the company is now in excess of 30,000,000 pounds per annum, and it is rapidly expanding to meet the requirements of the domestic and foreign trade. The plants of the company are at Buffalo, Brooklyn, Wappingers Falls, N. Y., Easton, Penn., Marcus Hook, Penn., and Frankford, Penn.

"The aim of the management," states a leading official, "is to manufacture coal-tar dyes and intermediates which can compete successfully, both in quality and variety, with those heretofore imported. As the constituent units of the new company include manufacturers of raw materials, of intermediates and of coal-tar dyes, the company in one organization covers the industry from raw material to finished products."

The offices of the National Aniline and Chemical Company, Inc., will be at 244 Madison avenue after July 1.

COAL-TAR CRUDES—Section II

The Estimation of Toluene in Crude Petroleum

S. E. Bowrey (Chem. Tr. J., 1917, 60, 425) performs this as follows: The first operation is the elimination, by distillation, of all constituents boiling above 150° C., then washing. The distillate is then washed free from unsaturated hydrocarbons by sulfuric acid, alkali and water. A modification of Edelmann's SO_2 process for refining lamp oil is then applied. Results obtained by the author on ten successive extractions with liquid SO_2, at 35°, of an artificial mixture by volume of 15 per cent. aromatic and 85 per cent. paraffin hydrocarbons, are tabulated. The aromatics consisted of equal percentages of benzene, toluene and xylene (5 per cent. each) in admixture. Evaporation losses in air totaled 27.8 per cent., on an average, of which aromatics formed but 0.57 per cent. The use of a vacuum reduced this error. Tests to determine the relative solubilities of the three aromatics showed a tendency for benzene to dissolve in preference to xylene.

The combined extract (50-100 c.c.), still containing about 20 per cent. of paraffins, is fractionated very slowly with the best form of stillhead. A regular, slow distillation is much more important than the type of stillhead. To obtain accurate fractionation by one distillation, an apparatus was designed whereby the vapor passed through a narrow orifice in the stillhead, and the resulting slight increase in pressure in the distilling flask operated a mercury cut-off for the gas supply.

The sp. gr. of the fractions is determined by a Sprengel tube, as a rapid and accurate method for estimating small amounts of paraffins remaining. The sp. gr. at 15° of benzene is 0.884, of toluene 0.870, and of xylene 0.865. That of paraffins is deduced from similar fractions of pure paraffin spirit, separately determined. Figures are reduced to percentages of the original petroleum. An example of the method applied to 1,800 c.c. of crude oil is given in steps, and the results are tabulated.

In these days of high-priced toluene more and more attention is devoted to the possibilities of utilizing the small amounts present in certain petroleums.

The "Cracking" of Solvent Naphtha

The employment of the Rittman and similar processes to utilize petroleum residues for the production, by "cracking," of gasoline as well as of benzene and toluene, has notably enlarged the possibilities of ample supplies of these hydrocarbons during normal conditions. At the present time price quotations show that we are far from meeting current needs. The availability of the more complex and higher boiling constituents of coal tar as material for transformation into benzene, and especially into toluene, becomes, therefore, a matter of some importance.

Clive M. Alexander, of Port Arthur, Texas, has patented a method (Amer. Pat. 1,230,975, of June 26, 1917) which is claimed to effect such a transformation, with a fair yield, by the use of solvent naphtha. This solvent naphtha is an important fraction of the distillation products of coal tar. It boils between 140° and 170° C., and consists chiefly of the xylenes, pseudo-cumene and some of their higher homologues.

In the Alexander process it is driven, in the form of vapor, through heated tubes or retorts maintained at temperatures ranging from 600° to 1,000° C. A temperature in the neighborhood of 800° is found to be the most favorable. Under these conditions the naphtha yields a condensed distillate equivalent to 70 per cent. or more of the volume of the original liquid. The best results are obtained when the rate of passage through the cracking apparatus is such that at least 70 per cent of distillate is collected from the effluent gases and vapors. This distillate contains further a volume of liquid boiling within the same limits of temperature of the original naphtha, and which can be submitted again to the operation of cracking equal to about one-third of the original amount. A rate of speed in feeding the apparatus, allowing this recovery of practically one-third of the original liquid, seems also to be a favorable factor. About one-third of the condensate consists of a mixture of benzene and toluene, boiling between 75° and 130°. The remainder consists of naphthalene, diphenyl and other high boiling aromatic hydrocarbons.

The net result, under the most favorable conditions, is that one-quarter of the solvent naphtha is transformed into benzene and toluene, and one-third is recovered to be used over again.

The inventor finds that the same method is applicable for transforming high-boiling tar oils in creosote oil into low-boiling phenols.

Improvement in Tar Distillation.

The Sulzer Frères Soc. Anon., of Wintherthur, Switzerland, (Eng. Pat. 105, 198, of 1916), have devised a new apparatus for the distillation of coal-tar, intended to lessen the degree of carbonization from prolonged contact with the heated walls of a still. The operation of distillation is carried on in a horizontal drum, the entire external surface of which is exposed to the heating gases. A series of scoops, carried on a rotating shaft, continuously raise the tar from the bottom of the drum and deposit it on the upper walls. The arrangement is such that no portion of the tar remains long in contact with any given area of the inner surface of the still.

New Form of Naphthalene for Use as an Insecticide.

John B. Barrett, of Annapolis Royal, Nova Scotia, proposes (Amer. Pat. 1,230,648, of June 19, 1917) a new form of preparing naphthalene, for use as an insecticide. The hydrocarbon constitutes the chief part of a mixture, containing 90 per cent. of naphthalene, 80 per cent. of naphthols and 2 per cent. of phenol. The mixture is applied as a coating to inert substances—small balls, or the like—and an additional coating of a mineral oil is added, to prevent too rapid volatilization.

COAL-TAR INTERMEDIATES—Section III

Remarkable Explosion in an Aniline Plant

There occurred in the works of the Marden, Orth & Hastings Company, on April 21, 1917, a remarkable explosion in a stripper employed to recover the aniline dissolved in wash waters.

An explosion in connection with this operation has hitherto been unknown. As the cause of the recent accident seems, thus far, without explanation, a full description of the explosion is of importance to all engaged in the production of aniline.

We quote the following account furnished by Mr. Richard S. Bicknell, of the company in question, to "The Journal of Industrial and Engineering Chemistry" (Vol. 9, p. 720, 1917):

Description of Stripper.

"The stripper is a ⅜-in. steel tank 7 ft. in diameter and 8 ft. ⅜ in. deep, flat bottom and plate cover on top, all ⅜-in. steel. To stiffen the cover two 6-in. I-beams (12¼ lbs.) 16 in. between centers were riveted on the cover. The cover was bolted to the flange with about forty ¾ in.x1½ in. bolts. The bolt holes are spaced about 6 in. apart on three-quarters of the circumference and 12 in. on centers on the remaining quarter. The bottom has a 2½-in. outlet, with a plug cock which runs to the sewer. The top has a 2½-in. inlet with a cross. The cross has a 2-in. inlet with a valve and a 1½-in. inlet with a valve. On the top of the cross was a ¾-in. level safety valve and gauge.

"The stripper has a closed coil of 2-in. pipe for the purpose of heating, 8 turns, welded, connected in through the side with cast-iron elbows and nipples to the coil.

"There is a 1½-in. valve and line feeding the top of the coil with steam, and the bottom drains through a ¾-in. steam trap.

"On the cover was a manhole and a 6-in. vapor line outlet running up vertically for 6 ft. to 3 2½-in. coil in a 4 ft. x 6 ft. wooden tank. The vapor line, coil and coil-outlet have no valve. The coil discharges into a steel separator 5 ft. x 6 ft. The aniline is drawn off the separator.

Operation Just Prior to the Explosion.

"The stripper was filled with aniline waters up to just 30 in. from the top of the stripper by means of a steam siphon from the wooden tank in the yard, which is used as a reservoir for aniline waters. At 4:30 P. M., April 21, 1917, the cover was placed on the manhole of the stripper, and the steam turned on the coil between 4:45 and 5:15 P. M. by a workman. The stripper is operated by simply distilling the aniline waters, condensing the aniline and water in a coil and running same into a separator. About 5:45 P. M. the stripper exploded. A workman was 10 to 20 ft. from the stripper when it went up, and was splashed with water, undoubtedly from the stripper; the water was warm, not hot, and he was not burned.

Results of the Explosion.

"The cover of the stripper was blown off with considerable force, breaking all the bolts which held it on by tension. The cover was bent and the flange of the stripper bent. The cover landed on the edge of the floor beside the stripper

"The entire contents of the stripper (1,600 gallons) were thrown out, leaving a layer of 1½ in. of iron sludge in the bottom of the stripper. A hole 20 ft. x 25 ft. was torn through the roof, and an 8-ft. I-beam bent 18 in. out of line. The wire glass windows which were near were broken. The stripper was not damaged very much. The same cover was replaced, and except for a few fittings was satisfactory for service again.

"After the explosion the inlet valve to the coil was found wide open, 4¾ turns. The condenser was clear. The two valves on inlets to the cross on the cover were closed.

Comments.

"The aniline waters were analyzed with the following results:

Sample	Feed water as put into stripper Per cent	Liquid from bottom of stripper after explosion Per cent
Aniline	3.13	3.07
Acidity (as H_2SO_4).....	0.005	0.09
Nitro Compounds	None	None

"The explosion behaved as though a layer of explosive had been placed on the bottom of the stripper. It is almost inconceivable that the explosion could have been caused by steam because the 1½ in. steam inlet is the only supply. If this were led into the stripper through a break in the coil the contents of the stripper would probably have been heated to boiling before exploding. Even then it is difficult to see how the steam at 115 lbs. would create such a sudden and violent explosion, entering as it did, and with the exit condenser coil wide open."

New Method for the Preparation of Crude Sodium Salicylate

W. Everitt & Co., Ltd., and W. Everitt, of Southall, Middlesex, Eng. (Brit. Pat. 105,612, of 1916) describe a new process for preparing crude sodium salicylate from which salicylic acid itself can easily be manufactured.

The essential feature is the use of a rotary autoclave into which the charge of sodium phenate is introduced. Carbon dioxide is admitted at ordinary temperatures during constant rotation until absorption has ceased. The pressure of the gas is then raised to 100 lbs. per square inch, and maintained at this point for some hours. The gas inlet is then closed, and the autoclave is heated to 120°-140° C. until conversion is complete.

Autoclaves, for the purpose, are jacketed, and connection is made with both steam and cold water supply. A hollow trunnion permits the entrance of carbon dioxide.

The Evolution of Trinitro-Toluene

In "Drug and Chemical Markets" for June 6, 1917, Dr. Bernhard C. Hesse, who has done so much to familiarize the public with the marked dependence of our national preparedness against invasion upon the expansion of the country's coal-tar chemical industry, gives a striking illustration of this connection, in a short account of trinitro-toluene, or trinitrotoluol as it is more generally termed. Incidentally, the powerful economic rôle of isomerism among the intermediates of the aromatic series is strikingly illustrated.

"With the fall of Liége in 1914, the world at large became acquainted with a new and powerful military explosive, and its cabalistic symbol, T. N. T., acquired a horrifying and world-wide significance almost over night.

"Although then new to the world at large, T. N. T. was in reality known as early as 1863, but as a mere laboratory product. Its explosive properties were not recognized nor utilized until about 1880, but no particular attention was given to it as an explosive until about 1891, when factory methods for making it and suggestions for its wider use in the explosives field, military and otherwise, were published in Germany. It is described for explosive purposes in English text-books as early as 1896; Spain and France, prior to 1909, had introduced it into their military services and German manufacturers had long before that been engaged in introducing it into the military services of other countries.

"This material, T. N. T., is neither difficult nor dangerous to make. It is transported with greater safety than almost any other high explosive. When compressed under 30,000 to 40,000 pounds per square inch, it can be worked and cut into suitable forms. Loose, it is a white solid, half again as heavy as water, melts well below the boiling point of water and can then be filled into shells without danger from fumes or corrosion of the metal. It is slightly less powerful than picric acid. While the latter frequently pulverizes a shell, T. N. T. generally bursts the shell into fragments large enough to have a destructive effect. Like picric acid, it is explosive by means of a fulminate and does not, if pure or in proper form, explode of itself.

"On treating toluol—a water-white liquid (a 'chemical cousin' of benzol)—with nitric acid, three general classes of compounds are obtained: Trinitrotoluol, (T. N. T.), dinitrotoluol and mononitrotoluol. The last two are used in making dyes. Trinitrotoluol is made by treating dinitrotoluol or mononitrotoluol with more nitric acid. Of the mononitrotoluol the dye maker uses two different kinds, designated as ortho and para-mononitrotoluol, respectively. In making the ortho variety it is always accompanied by more or less of the para variety, and the reverse is also true At about the end of the nineties the situation was that more para was necessarily made than the world's dye market could consume, and more ortho could be used for dyes, if it could be had without making more para, or if a new outlet for para could be found. At that time the German dye makers were burdened with not less than 15,000 long tons of para, for which they were unable to find any use. This para costs about $180 per long ton to make, and this surplus meant about $2,700,000 of idle money. Worse than that, this was irresistibly growing at an alarming rate. Until about 1904 the German dye makers were most energetically, almost frantically, endeavoring to find new outlets for this para in the dye business, but without any real success. Then their feverish activity stopped short, ominously so. Liége, in 1914, gave the answer! These 15,000 tons of para, and all surplus that was since made, found their way into T. N. T. More than that, since 1904 or thereabouts the Germans have actually developed methods that gave much more para for a given weight of ortho than the older processes; they wanted this extra para for explosives.

"That Germans have employed T. N. T. as an explosive rather than picric acid is a logical outcome of industrial conditions in their land. Germany has never been so well placed as France, Belgium or Great Britain for large supplies of carbolic acid from which picric acid is generally made. As regards toluol, she has for years been better placed than these other countries. With this excess burden of para-nitrotoluol on her dye makers' hands, Germany seems to have taken the line of least resistance and made the most of her situation. Clearly, the German dye makers were actually driven into the explosives field; and seemingly they did not enter it as a result of any long-headed foresight on their part or on the part of their government. It took them thirty-seven years to get into the explosives field after the material for T. N. T. was accessible to them and to their government.

"In any event, the world has been taught a striking, if horrifying, object lesson, to what extent a domestic coal-tar dye business can aid national defense, even if through a flukish combination of circumstances. This is certainly good ground for the thought that, by intelligently and systematically exploiting the dye field further, an important national aid in the line of explosives, medicinal remedies, disinfectants and the like can be developed."

Recovery of Picric Acid From Wash-Water.

Henry A. Gardner, of Washington, D. C., patents an improvement upon the current methods of recovering picric acid from wash-water (Amer. Pat. 1,231,000, of June 26, 1917). Sodium bisulfate is added to the wash-water in sufficient amount to form a high-gravity solution. The picric acid present separates out in a flocculent form, forming a supernatant layer, which can be easily removed.

Separation of Aromatic Sulfonic Acids from Sulfuric Acid and their Technical Preparation in a Solid Form

It is not the industrial practice to separate the sulfonic acids of aromatic hydrocarbons, especially when destined for use in preparing hydroxy derivatives.

The usual commercial method of producing b-naphthol, for example, in the course of which naphthalene-b-sulfonic acid is formed but not isolated, has been as follows: Naphthalene is heated with an excess of concentrated sulfuric acid to 160° C. for a sufficient length of time to convert the naphthalene into naphthalene-b-sulfonic acid, in the presence of an excess of sulfuric acid. Lime is added to this mixture of sulfuric acid and naphthalene-b-sulfonic acid, forming calcium sulfate and calcium naphthalene-b-sulfonate. The difficultly soluble calcium sulfate is separated in solid form from the solution of the calcium sulfonate by filtration. This method of the separation of the two salts is, however, not sharp. To avoid appreciable loss of the calcium naphthalene-b-sulfonate, it is usually necessary to repeatedly wash the calcium sulfate with water in order to remove the sulfonate adhering thereto. Sodium carbonate is added to the solution of the calcium naphthalene-b-sulfonate, whereupon that compound is converted into sodium naphthalene-b-sulfonate and calcium carbonate is precipitated. The sodium sulfonate is readily soluble in water, while calcium carbonate is insoluble. Separation of the two salts may therefore be effected by treatment with water and filtration. The dilute solution of sodium naphthalene-b-sulfonate is then evaporated to dryness and the resultant solid is fused with sodium hydroxide, which converts the salt into sodium b-naphtholate. B-naphthol is liberated by treatment with a suitable acid, such as sulfuric acid.

It will be observed that the excess of sulfuric acid, which has not reacted with the naphthalene, is converted into the comparatively valueless calcium sulfate and thus lost.

Professor Louis M. Dennis, of Cornell University, has perfected a method (Amer. Pat. 1,228,414, of June 5, 1917), which materially simplifies the whole procedure in the manufacture of this class of compounds. It is as follows:

The mixture of naphthalene b-sulfonic acid and sulfuric acid, formed as above stated, is treated with a solvent such as toluene, which has the property of dissolving the sulfonic acid, but not of dissolving any appreciable amount of sulfuric acid. Toluene also possesses the property of dissolving an appreciably greater amount of naphthalene-b-sulfonic acid at 100° C., than it does at a low temperature, such as 5° C. The hot solution of the sulfonic acid in toluene, which separates from the residual sulfuric acid in a distinct layer, is removed and cooled, whereupon the naphthalene-b-sulfonic acid separates out from its solvent in solid form, and is freed from the toluene by filtration. Cooling to 5° C. gives good results. The solid naphthalene-b-sulfonic acid is then freed from any small amount of the solvent which may still adhere to it, either by evaporation, or by subjecting it to the action of a centrifugal. It may then be sold as such or further treated to produce naphthol.

To convert it into naphthol, its sodium salt may be prepared by adding to the acid, obtained as above, the calculated amount of sodium hydroxide, or sodium carbonate, and then fusing with the calculated amount of sodium hydroxide to form sodium b-naphtholate. This latter may be treated with an acid, such as sulfuric acid, in the usual way, to form b-naphthol. If the sodium sulfonate is in solution, the water must, of course, be removed before the fusion.

An alternative method is to add the acid directly, in dry form, to the solid sodium compound, the latter being in an amount sufficient to convert the sulfonic acid to sodium b-naphtholate, when the mixture is heated to the proper temperature. In this latter case sodium naphthalene-b-sulfonate is not formed separately. B-naphthol may then be formed from the sodium b-naphtholate, thus obtained, in the usual way.

The solvent, toluene, after being freed from the sulfonic acid, may be used again in the extraction of further portions of the acid from fresh mixtures. The sulfuric acid which remains after the sulfonic acid has been removed from it by the solvent, is drawn off and used for any desired purpose.

It is obvious that solvents other than toluene may be used to dissolve the sulfonic acid, provided they have the property of dissolving said acid, but of not dissolving any appreciable amount of sulfuric acid, and of dissolving appreciably greater amounts of sulfonic acid at high temperatures than at low temperatures. It is also of advautge if the solvent is not miscible with water to any appreciable degree.

It is further obvious that the invention has general application to the sulfonic acids of the hydrocarbons of the aromatic series.

B-Naphthol Derivatives for Disinfection Purposes.

The use of chlorinated and brominated derivatives of b-naphthol in the preparation of disinfecting solutions is described by H. Bechold, of Frankfurt a. M., Germany, assignor to the Chemische Fabrik Ladenburg (Amer. Pat. 1,232,187, of July 3, 1917). Compounds containing three or four halogen atoms in the molecule yield the best results. They are dissolved in an alcoholic solution of potash soap, and this is diluted with water, yielding a milky solution, prior to application for disinfecting purposes.

Diseases Incident to the Manufacture of High Explosives

The abnormal demand for high explosives, developed in this country during the past three years, led to the hasty construction of numerous works, and an equally hasty organization of the mechanism for producing vast amounts of nitro-derivatives of the aromatic hydrocarbons. Prior to the war explosive manufacture in the United States had been largely limited to what is known as peace explosives, and the "occupational diseases" incurred in plants of this kind were of relative unimportance.

There is but little danger to the workers from fumes in the processes that take place in the manufacture of black gunpowder and nitroglycerine. What danger there was had been studied carefully by physicians during the many years of the operation of the industry in this country and precautionary measures devised. But the necessity of haste in turning out great quantities of picric acid and trinitrotoluene as well as the nitric acid, and other substances used in the manufacture of high explosives, caused the hurried erection of plants poorly designed for the work, and the neglect of many precautions for the safety of operatives that had been in use in the plants in other countries where such manufactures had been carried on for many years. So many workers were incapacitated, permanently disabled and killed by industrial poisoning, while engaged in the manufacture of explosives, that an investigation of these plants was instituted by the United States Department of Labor and resulted in some surprising discoveries.

A study was made of forty-one plants, employing 90,000 workers, approximately 30,000 of these workers being women. In one of these plants it was found that to maintain a working force of 200 it had been necessary to employ a total of 4,000 workers during a period of thirteen months. Many of the buildings used had been constructed with poor provision for ventilation, so that the employees were frequently driven into the open by the fumes arising from the chemicals, and cases of lung poisoning and skin diseases were frequent. In the production of trinitrotoluene, a substance almost unknown in this country prior to the war, toxic jaundice had became prevalent among the workers, some of the cases developing fatalities. It was found that in twenty-eight plants, in the space of about one year, there were 2,507 cases of industrial poisoning, of which seventy-five were women. Of the total number of cases fifty-three were fatal, two of these being women. About 55 per cent. of the total cases and 53 per cent. of the fatal cases were caused by nitrogen oxides and nitric acid, while 28 per cent. of all cases and 25 per cent. of the fatal cases were due to trinitrotoluene, or TNT, which is manufactured and made into charges for high explosive shells.

An extremely dangerous process is the filling of shells with trinitrotoluene, either by pressing, which is very dust productive, or by molding, which involves fumes.

The reason nitrogen oxide poisoning or "fume sickness" heads the list is that all of these explosives are produced through processes of nitration in which a mixed acid is used, one of the ingredients being sulfuric acid and the other nitric acid. The higher the nitration the greater the danger from fumes. The 1,300 to 1,400 men who suffered from these fumes were employed in making nitrotoluenes, nitrobenzenes, nitro-naphthalenes, nitroglycerine and the nitric acid used for these processes.

The alcohol and ether, used in the manufacture of smokeless powder, threw off fumes which often resulted in making the men drunk, what is known as an "ether jag" being a common occurrence among the men engaged in the handling of these liquids. Before physicians had taken up the study of this phase of the business several men had been taken to the hospital and had their trouble diagnosed as intoxication, owing to the odor of alcohol on their breaths. One man, suffering from an over-inhalation of ether fumes, died shortly after being taken to a hospital, and the physician in charge gave the cause of his death as acute alcoholism.

Although the number of women employed in the various plants is large, 30,000, care has been taken in the majority of cases to have their field of labor confined to such processes as are not especially dangerous. As a result, the number of cases of industrial poisoning among female workers has been small in proportion to the number of men who have been attacked by gases.

Many manufacturers fell into the error that was so prevalent in English plants, in the early period of the war—that of working the men twelve or fourteen hours in the effort to stimulate production. Fatigue sensibly diminishes the powers of resistance to disease, and many workers in these plants were incapacitated through occupational diseases.

Physicians who have made a study of the effects of poisoning resulting from the manufacture of explosives state that the use of proper precautions will obviate much of this industrial poisoning. They advocate the use of masks and respirators by men engaged in the production of nitro compounds, such as trinitrotoluene and nitrobenzene, which throw off dangerous fumes, and the adoption of forced and rapid ventilation in all plants used for the manufacture of explosives. In addition, the best of sanitary facilities should be provided for the use of employes, and care be taken that none of the men become so fatigued by overwork as to lessen their powers of resistance to poison.

Valuable studies in this connection are found in the "Symposium on Occupational Diseases in Chemical Trades," published in the Journal of Industrial and Engineering Chemistry, 1916, *8*, 1054, and in the article on "Munition Plant Poisons," by A. Rice, in the American Journal of Public Health, 1917, *7*, 273.

C. W. Hancock, in the Canadian Chemical Journal, 1917, *1*, 33, also furnishes a helpful study on the same topic. In his opinion the ordinary hazards to industrial health are: (1) defective illumination, (2) poor ventilation, (3) long hours, (4) factory sanitation. The specific hazards of the chemical industry are: (1) superficial poisons, irritant and corrosive, such as alkalies and mineral acids; (2) blood poisons, such as CO and nitrobenzene; (3) poisons with definite internal action, which are again classified by their physical characteristics as poisonous dusts, fumes or liquids. The specific effects of a number of fumes, gases and other poisons are given, especially the action of aniline, which causes more industrial poisoning than any other organic compound, and methods of prevention and cure, are given in detail.

Analytical Studies

Among recent analytical studies on coal-tar compounds the following are of special interest:

"Aniline Method for the Estimation of Mineral Fillers in Rubber," O. H. Klein, J. H. Link and F. Gottsch, J. Ind. Eng. Ch., 1917, **9**, 140.

"Estimation of Phenol in Tar Oil Phenols," R. Masse and H. Leroux, Bull. Soc. Chim., 1917, **21**, 2; Analyst, 1917, **42**, 212.

"Action of Aromatic Amines on Fatty Acids," E. de Conno, Gazz. Chin. Ital., 1917, **47**, 93; Analyst, 1917, **42**, 213.

"Identification of Acids, II. Organic Acids," J. A. Lyman and E. E. Reid, J. A. C. S., 1917, **39**, 701.

"Analysis of Sulfonated Oils," W. K. Alsop, Report of 1917 Committee, J. Leather Chem. Assn., 1917, **12**, 266.

"Preparation of Diphenylamine Sulfuric Acid Reagent for Nitrates," W. Tonius, Z. Nahr. Genuss., 1916, **31**, 322; Analyst, 1916, **41**, 314.

"Modification of Price's Method for Separation of the Seven Permitted Coal-Tar Dyes to Include Tartrazine," C. Estes, J. Ind. Eng. Ch., 1916, **8**, 1123.

Theoretical Studies

During recent months the following results of research on coal tar derivatives, which possess more or less interest for the technical chemist, have appeared in various publications:

"Catalytic Action of Dyes on Formation of Colloidal Gold," I. Traube and N. Takayasu, Intern. Z. phys. chem. Biol., 1916, **2**, 453; J. Chem. S., 1916, **110**, 479.

"The Bucherer Reaction," H. Franzen and H. Kempf, Ber. 1917, **50**, 101; Abs. J. Chem. Soc., 1917, **111**, 262. After testing a number of acids it is concluded that the hydrolysis of aromatic amines is governed by the degree of non-saturation of the acid rather than by its strength.

"The Bisulfite Compounds of Azo Coloring Matters," N. N. Voroshcov, Ann. Chem., 1916, **6**, 381 and 293; Abs. J. C. S., 1917, **111**, 300.

"Relation Between the Chemical Constitution and Color of Azo Compounds," A. C. Sircar, Chem. Soc. Trans., 1916, **109**, 757; J. S. C. I., 1916, **35**, 960.

"The Heat of Combustion of Toluene," T. W. Richards and H. S. Davis, J. A. C. S., 1917, **39**, 341; Analyst, 1917, **42**, 220.

"Para-Quinoid Constitution of Pyronine," J. v. Braun and E. Aust, Ber., 1916, **49**, 989; Abs. J. S. C. I., 1916, **35**, 732.

"Investigations on the Production of Phenol by Microbes," A. Berthelot, Compt. rendus, 1917, **164**, 197; Off. Int. d'Hyg. pub., 1917, **9**, 530.

"Optical Activity of Low Temperature—and Generator—Coal-Tars," F. Fischer and W. Gluud, Ber. 1917, **50**, 111; Abs. J. S., 1917, **111**, 258.

"Preparation of O-Chloro-Toluene" (Ger. Pat. 294,638) (Bad), J. S. C. I., 1917, **36**, 286; Abs. J. C. S., 1917, **111**, 258.

"A New Benzanthrone Synthesis," A. Schaarschmidt, Ber. 1917, **50**, 294; Abs. J. C. S., 1917, **111**, 274.

"Spectrochemistry of Benzene Derivatives," Cinnamic Esters, etc., K. v. Auwers, Ann., 1917, **413**, 253; Abs. J. C. S., 1917, **111**, 266.

Toxicity of Benzene Derivatives to Insects.

W. Moore, J. Agr. Research, U. S. Dept. Agr., 1917, 9, No. 11,371, has made an exhaustive study of the toxicity of various benzene derivatives to insects. The vapor of 28 benzene derivatives was tested in this connection. The list included the CN, Cl, Br, I, OH, NH_2, CHO, NO_2, and CH_3 compounds of phenyl, the $(CH_3)_2$, Cl_2, Br_2, OHCl, $OHNO_2$ and OH CHO, the ortho and para $Br.CH_3$, ortho, meta and para $CH_3.OH$ and ortho $NO_2.CH_3$, benzyl alcohol—CH_2OH, benzoyl chloride COCl, $(CH_3)_3Br$ and $(CH_3)_3NO_2$ compounds. CS_2 was used for comparison with benzene compounds and furfural for comparison with aldehydic compounds.

The method consisted in exposing 5 house flies, in a corked liter flask at 70° F., for 400 min., or until dead. Results were calculated to millionths of a gram molecule, and reported in tables, and graphically by curves and blockings. The work is summarized as follows: (1) All compounds are more toxic than CS_2. (2) The physical character, boiling point, and vapor pressure, have more influence than chemical composition. (3) Up to 250° C., the higher the boiling point the greater the toxicity. Beyond 250° C. there is insufficient volatilization. (4) Lipoids are soluble compounds of low boiling point, and less soluble in those of high boiling point. (5) Compounds of low boiling point, though less toxic, may give better results because of volatility, especially in the fumigation of grain.

The experiments were undertaken in the hope of finding an insecticide, toxic to insects, while nontoxic to animals or plants. In a previous paper (J. Econ. Ent., 1917, 9, 71), the author pointed out the possibility of fumigating animals with nitrobenzene to destroy external parasites. Literature is cited at the end of the article.

Determination of Carbolic and Salicylic Acids in Antiseptic Gauze and Cotton.

J. B. Krak (Chem. Analyst. 1916, 17, 14) gives the following directions for determining the amounts of carbolic acid and salicylic acid in tissues for antiseptic use: Into a casserole weigh about 5 g.material, add 55 c.c. N NaOH, cover and heat on steam bath for 15 min. Filter, while hot, on a tared filter, and dilute filtrate and washings to 500 c.c. Wash the residue on filter with dil.HCl, alcohol and ether, dry at 100° and weigh. Into a glass-stoppered bottle pipette 100 c.c. Br solution, add 25 c.c. HCl, after 5 min. add an aliquot (100 c.c.) of the extract, after 5 min. add 4 g.KI, and after another 5 min. titrate 1 with N/10 thiosulfate. Tribromo products are formed. The bromide reagent is made by dissolving 2.5 g.$NaBrO_3$ and 25 g.NaBr in a liter of water, and is standardized by placing 25 c.c aliquots in a glass-stoppered bottle, adding 10 c.c. HCl (1:12) after 5 min. adding 3 g.KI and 5 min. later titrating with N/10 thiosulfate.

The Manufacture of Dimethyl-aniline, Monomethyl-aniline, Diphenylamine and Their Homologs.

In the Oil and Color Trade Journal, 1917, 51, 1892, two old autoclave processes for the manufacture of dimethyl-aniline are discussed. Full details are given for the Bardy process using aniline, methyl alcohol and sulfuric acid, and for the Brigonnet method using methyl chloride and slaked lime. The former method, with less methyl alcohol, is used for the production of methyl-aniline. The Girard and de Laire process for the manufacture of diphenylamine from aniline and aniline salt, and also a method similar to that of Bardy, for making diphenylamine, are outlined. Plans, sections, diagrams and descriptions of apparatus accompany the article.

Nitro-Carbazole.

The Actien-Gesellschaft für Anilin-Fabrikation, of Berlin (Ger. Pat. 295,817, of Nov. 6, 1912) describes a method for preparing 3-nitro-carbazole and its halogen derivatives by treating carbazole, or its halogen substitution products, with about two molecules of nitric acid, of 10 per cent. concentration.

ARTIFICIAL COLORS—Section IV

The Examination of Food Coloring Substances

W. E. Mathewson (J. Off. Agr. Ch., 1916, 2, 164) contributes a valuable study on this subject. It includes a brief discussion on pigments, soluble coloring matters and oil-soluble dyes. Methods for the separation of the eight permitted coal-tar dyes by the use of immiscible solvents follow. Outlines of methods of separation for basic and acid dye groups are briefly considered. The reactions of some of the commoner dyes with hydrochloric and sulfuric acids, sodium hydroxide and ammonia are tabulated as in Allen's Commercial Organic Analysis, Vol. V. A few special tests for the permitted colors, also very similar to the reactions given in Allen, page 647, are followed by methods of separation and identification of natural coloring matters. The tests and reagents are the same or modifications of those appearing in the literature. The results of a few tests on thirteen natural colors are tabulated, and the paper concludes with some modifications of old established tests of four common natural colors and a useful bibliography.

In Bulletin No. 448, of the U. S. Department of Agriculture, 1917, the same author contributes a fuller paper on "The Separation and Identification of Food-Coloring Substances," which includes in addition to the matter mentioned above a detailed method of separation for the colors commonly occuring in foodstuffs when the permitted colors are not used, an abridged procedure for the permitted dyes, and an extended table for the separation of food colors, giving the extraction value of three immiscible solvents, amyl alcohol from salt solution, from acid solutions of varying strengths, amyl alcohol-gasoline mixture from acid solution, ether from neutral acid and alkaline aqueous solutions, and dichlorhydrin from salt solution.

Tabulated results of reactions of dyed fiber with four reagents, two acid and two alkaline, follow, and also a table showing results obtained on the solution by a reducing agent followed by an oxidizing agent. Schmidt's oxidation test with bromine is discussed fully and table of results given, also the reactions of the dyes with nitrous acid and coupling with a-naphthol and their behavior when warmed with KCN. Brief reference is made to natural colors, repeating the reactions to a large extent found in the preceding paper.

New Azo Insoluble Dye.

The "Badische" Company (Ger. Pat. 295,025) describes a new dyestuff obtained by coupling aceto-acetic ester with diazotized 1-amido-anthraquinone.

Artificial Dyestuffs as Antiseptics

The vastly increased demand for effective antiseptics, in connection with war surgery, has notably stimulated the study of the availability of various coal-tar dyes for the purpose in view. British surgeons unite in regarding the acridine dye, trypaflavine, patented in 1910 by Cassella and Co., as by far the most useful antiseptic now at their service.

A solution of 1 :1,000 in water is sufficiently powerful. This is 1/400 the strength harmful to the body, and is equivalent to 80 per cent. phenol. Other antiseptics, strong enough to attack disease germs, have a bad effect on the tissues and lower the power of the blood corpuscles to repel infection. Flavine actually increases the efficiency of the phagocytes. In the presence of serum it is the most potent bactericide for stapholococcus, B. coli, enterococcus, anaerobes, etc. Its germicidal power is twenty times greater than that of $HgCl_2$, and 800 more than that of phenol. Licenses will be issued in England (probably without royalty) to Blandy Bros. and Levin stein for the manufacture of the product.

New Dyestuffs from 2.5.7-Amino-Naphthol-Sulfonic Acid

The Chemische Fabrik Griesheim-Elektron in a recent patent (Ger. Pat. 295,767, of Feb. 5, 1914), describes a new series of acyl derivatives of 2.5.7-amino-naphthol-sulfonic acid, obtained by condensing it with 2.3-hydroxy-naphthoic acid halides, or with their o-acetyl compounds. The products have a strong affinity for both animal and vegetable fibers. The leading derivative, 2.3-hydroxy-naphthoyl-2-amino-5-naphthol-7-sulfonic acid, yields in alkaline solution the characteristic yellow tint of the aryl-amino alkali salts of 2.3-hydroxy naphthoic acid. Cotton absorbs it readily from alkaline solution, and silk from acetic acid solutions. It combines easily with two molecules of diazo compounds, and a variety of colors, all fast to washing, are obtained by exposing to the action of diazo compounds fabrics which have absorbed the sulfonic acid.

Artificial Dyes in Forensic Analysis and Microscopic Technique.

E. Fuld (Bioch. Leitsch., 1917, *70*, 241), furnishes details on the utilization of Rhodamine and of Malachite Green in the detection of blood. A variety of new stains for microscopic work, derived from Methylene Blue, are described by L. Tribondeau and J. Dubreuil Compt. rendus, 1917, *164*, 551).

Proposes Modifications in the Tariff on Artificial Colors

During the hearings before the Senate Committee on Finance, in connection with the legislation for War Revenue, Mr. A. H. Weed, counsel for the Manufacturing Chemists' Association, presented a forcibly worded brief, calling for the elimination from section 501 of the tariff act of September 8, 1916, the parenthetical exception therein contained, by which the specific duty of 5 cents per pound is made inoperative in the case of "natural and synthetic alizarin and dyes obtained from alizarin, anthracene, carbazole and natural and synthetic indigo and all indigoids whether or not obtained from indigo." This class of colors, excepted from the operation of the act, constitute 27 per cent, in value, of all the dyes sent out from Germany to the United States in 1913, and the German exports then represented more than 80 per cent of the American consumption of all synthetic colors. To emphasize the importance of this criticism, Mr. Weed shows that of the 101 newly invented dyes since 1906, 74 per cent come within this exception. Of the tonnage of these new dyes, imported in 1913-14, 90 per cent come under this exception. These dyes are all adapted to displace the older aniline colors, and come into direct competition with them. It has been claimed that all sulfur dyes, which are the largest group developed thus far by domestic manufacturers, would evade the special tax and fall under the exception.

These statements were placed before the Finance Committee in calling attention to the need to amend the act of September 8, 1916. He points out the provision that the special duty shall cease unless an American industry shall have been built up in five years' time from September, 1916, capable of furnishing 60 per cent in value of the country's consumption. He shows that the percentage of colors excepted will have also added to it 90 per cent of the business developed in the new dyes.

"Thus," says Mr. Weed, "the American manufacturer in his race to attan 60 per cent. of the American consumption, in order to obtain the surtax provided for in the act, will be competing against the foreign producer who can defeat this object by obtaining considerably less than 40 per cent. of the business."

To accomplish the purposes set forth above Mr. Weed proposed an amendment to the act of September 8, 1916, to which he hopes to have the committee give favorable consideration.

The Use of Coal-Tar Dyes on Leather

Several recent papers give much information of value in regards to the use of artificial dyes on leather. They are here briefly abstracted:

"Skins for Fancy Leather Purposes" (The Leather Manufacturer, 1917, 28, 117) Various methods for the treatment of fancy leather for specific purposes are discussed at length. Processes for white leather and coloring quebracho tans, using titanium potassium oxalate, phosphines, and other coal-tar colors are given. Methods for dyeing skins black, blue or purple with acid blacks, or blue and purple with basic dyes, and of producing black grain and white flesh by sumac and acid treatment, followed by brushing with a basic black, are outlined.

"Drenching, Pickling and Tanning Skins for Fancy Leather" (The Leather Manufacturer, 1917, 28, 118). The preparation of leather for fancy coloring effects is described, and the dyeing of the same with marbled, spray and changeant effects. The tannage method admits of dyeing many beautiful shades and making stains suitable for special purposes.

"Bleaching and Coloring of Dark Vegetable-Tanned Leather" (The Leather Manufacturer, 1917, 28, 126). A treatment for removing excess color and preparing leather for the dyeing process is described in detail, followed by the actual dyeing or coloring process. Titanium potassium oxalate as a softener and whitener, and basic aniline dyes set with bichromate of potash are used.

Dyestuffs for Leather

The American Leather Chemists Association has a committee on dyestuffs, consisting of Messrs. Kressman, Wisdom, Orthman, Klober and Creese, which is actively engaged upon studies for establishing the comparative values of coal-tar colors for use on leather. Their report, submitted at the Fourteenth Annual Meeting of the association, appears in its "Journal," 1917, 12, 279.

As a preliminary trial of strength and quality of color, 1:50,000 solutions in water were compared with standards. The depth and hue produced by dipping filter paper in solutions were also compared.

Dyeings were then made on wool and cotton yarn and on leather by methods previously worked out by the committee. Methods are given for applying acid, basic, mordant and direct dyestuffs on cotton and wool yarn, and for acid, basic, direct and chrome dyestuffs on leather. Methods for calculating results are illustrated also, and necessary directions follow for the preparation of the leather and the other materials used in dyeing tests. The results obtained by the authors are tabulated and conclusions drawn as follows: (1) The leather test is unreliable as a means of valuation. (2) A mechanical tumbler is required to insure constant circulation and temperature. (3) Adjacent pieces of leather, of the same surface and weight, should be used. (4) Yarn dyeing shows not less than 5 per cent. differences. (5) For fine distinctions, to determine money value, the only reliable test is on textiles. (6) Some method of dye testing on leather should be worked out in preference to the test on textiles.

Papers on Dyeing

Color chemists will find valuable reading in the following papers:—

The Pyrone Colors, A. E. Everest, J. Soc. Dyers, 1917, *33*, 78.

Capillary Phenomena and Their Importance in Technical Processes, S. A. Shorter, J. Soc. Dyers, 1917, *33*, 78.

Chemistry of the Sulfide Dyestuffs, F. M. Rowe, J. Soc. Dyers, 1917, *33*, 9.

On the Distribution in Dyeing of Direct Colors Between Fiber and Solute, Knecht and Hibbert, J. Soc. Dyers, 1917, *33*, 9.

Dyeing and Cleaning, D. B. Lake, J. Phys. Chem., 1916, *20*, 701.

Better Use of Tanning Materials, Adaptation of Materials, Leather Mfr., 1917, *28*, 119.

The Application of Resorcin in Dyeing and Printing with the Basic Colors, A. Wossnessensky, J. Soc. Dyers, 1916, *32*, 278.

Black Dyeing on Tussah Silk, R. N. Sen, J. Soc. Dyers, 1916, *32*, 243.

Production of Aniline Black on Wool, R. N. Sen, J. Soc. Dyers, 1916, *32*, 244.

Dyeing Wool With Sulfide Colors, R. N. Sen, J. Soc. Dyers, 1916, *32*, 245.

The Artificial Coloring of Woods by Means of Dyes, Forestry Bur., U. S. Dept. Agr.

Methylene Blue as a Reagent in Chemical Analysis, A. Monnier (Arch. Sci. phys. nat., 1916, *42*, 210; Analyst, 1917, *42*, 51), describes a method in which Methylene Blue is applied successfully to the detection and estimation of perchlorates in Chile saltpeter.

A Rapid Method for Comparing the Decolorizing Efficiency of Charcoals, L. Wickenden and J. W. Hassler (J. Ind. Eng. Ch., 1916, *8*, 518), describe a method based upon the use of solutions of Sudan III or Oil Red RX in kerosene. Filtration is rapid and the filtrates are clear and bright. The preparation of a standard scale for classifying charcoals, and a simple colorimeter which aids the process, are described.

New Black Sulphur Dyes.

H. R. Vidal, of Asnières, France (Eng. Pat. 105,162, of 1916), prepares a new series of sulfur dyes from the p-amino derivatives of phenol, o-cresol or m-cresol. Any of the above may be heated with about half of its weight of either resorcinol or m-phenylene-diamine in the presence of sulfur. The apparatus employed is provided with a reflux condenser, so that condensed vapors continually flow back into the molten mass.

Vidal's Black, the pioneer of the various sulfur blacks, discovered in 1893, was obtained by the simple fusion of an amino-phenol with sodium polysulfides.

New Lakes in the Dihydro-anthraquinone Series.

Various lake colors are obtained by Meister Lucius and Brüning (Ger. Pat. 294,830) by precipitating the leuco compounds of n-dihydro-1.2.2^1.1^1-anthraquinone-azines through acetification of the vat solutions and subsequent oxidation.

NATURAL DYES—Section V

A New Dyeing Machine

Henry Higgs, of Amsterdam, N. Y., in a recent patent (Amer. Pat. 1,229,612, of June 12, 1917), assigned to the Klauder-Weldon Dyeing Machine Co. of Amsterdam, describes a new machine for use in both washing and dyeing.

The device is of a somewhat complex nature. Essentially it consists of a rotary member, composed of several compartments adapted to contain textile materials. These compartments are formed by longitudinal concavo-convex walls (the concavity of one wall facing the convexity of an adjacent wall), transverse end walls and peripheral walls. The machine is placed in a vat, provided with the requisite gear and transmission to cause rotation, and is continuously submerged during rotation.

The walls of the machine consist largely of perforated plate or of wire gauze. The peculiar construction, better understood by a study of detailed drawings, is such as to give to materials placed in the various compartments a rolling or epicyclic movement. It is claimed that this favors the penetration of the textile fabrics by dye liquor at every angle. The uniformity of the work and the rapidity of the operation are very distinctly heightened.

Dyestuffs from Yacca Gum and Congo Resin.

G. H. Frank, of Leeds, Eng. (Eng. Pats. 105,118 and 105,119, of 1916), obtains azo and sulfur colors from the Yacca gum (derived from *Xanthorrhoea arborea* and *X. hastilis*), and from Congo resin derived from *Hymenaea verrucosa* and *Copaifera copallina*). Yacca gum reacts with diazo or tetrazo compounds, for example, with diazotized sulfanilic acid in alkaline solution, and yields products which dye silk and wool yellow shades. They are susceptible of after-treatment with mordants. Such azo compounds, or the nitro and nitroso derivatives of yacca gum or of Congo gum, are readily transformed into sulfur colors by fusion with alkaline sulfides or polysulfides.

SYNTHETIC DRUGS AND PERFUMES PHOTOGRAPHIC DEVELOPERS—Section VI

Death of Alois Von Isakovics

The death, on June 5, at his residence in Monticello, N. Y., after a comparative short illness, of Alois Von Isakovics, removes from the ranks of American chemists a genuine leader in the field of synthetic perfumes and flavors.

Born at Prag, Bohemia, on July 20, 1870, the son of a distinguished officer in the Austrian army, he came to the United States in 1886. Not long afterward he devoted himself to the preparation of organic perfumes and allied compounds, especially those of synthetic origin. He built up an extensive business in this field, and gained a reputaion for the purity of his compounds which led to extensive relations with other countries. Von Isakovics combined in a rare degree high scientific attainments and remarkable technical and administrative ability. At the time of his death he was unquestionably the leading authority in this country on the subject of synthetic perfumes. His studies on the subject are to be found largely in the pages of the attractive "Synfleur Herald," issued from the Synfleur Scientific Laboratories at Monticello.

He lectured on the subject regularly in the chemical courses of Columbia University, and contributed a valuable chapter on "Essential Oils, Synthetic Perfumes and Flavoring Materials" to the "Industrial Chemistry," recently issued by Rogers and Aubert.

In 1895 he married Marie Upshur, descended from a prominent Southern family. His wife was closely associated with him in the evolution of his model perfume works at Monticello, and will direct them in the future.

Salvarsan

There is much interest shown in the recent establishment of a factory in Brooklyn for the regular manufacture, under the Ehrlich patent, of salvarsan, by the H. A. Metz Laboratories, Inc. It is claimed that the company will be able to sell the domestic product at one-half of the prices which have prevailed for the German article. The latter has been sold regularly at the rate of $6 for each ampule of 1.5 grams. Every effort has been made to restrict its sale to the medical trade and hospitals. Despite all precautions a certain quantity has come into the hands of speculators who demand double the normal price. The H. A. Metz Co. expects to place its product upon the market during the latter half of July. The works are under the direction of Dr. G. P. Metz, who has made an exhaustive study of every phase of the manufacture at the factory in Hoechst, Germany, which has hitherto met the world's demand. He has a staff of four chemists, and will employ about 100 operatives.

Sodium Phenetidino-methane-sulfonate.

P. Lepetit, in the Atti R. Accad. Lincei, 1917, [v] 26, i, 126 and 172, gives an extended study of the action of alkalies and acids upon sodium p-phenetidino-methane-sulfonate, known better under the name of nevralteine patented in 1908). Alkalies split off formaldehyde and sodium bisulfite, causing a condensation of two molecules to the imide. Other aryl amino-methane-sulfonates undergo the same transformation. The reaction offers a good general method for preparing imides. Boiling with dilute hydrochloric acid brings about the formation of a base, C_{18} H_{20} O_2 N_2, crystalline, melting at 140° C., and possessing marked anesthetic properties.

Limited Use of Saccharin Now Permissible in France.

For 15 years the use of saccharin in France has been prohibited by law. A recent decree allows the use of the artificial sweetening agent and similar products in the preparation of the following articles: Sparkling wines, liqueur wines, except wines intended for the manufacture of medicinal wines; cider and perry; liqueurs, except liqueurs for the export trade; lemonade, and coffee and tea for drinking.

An internal revenue tax of $17.50 per pound is imposed upon saccharin at the place of manufacture.

Current Production of Synthetic Perfumes.

The manufacture of artificial perfumes is seriously hampered at present by the increasing difficulty in securing some of the more important ingredients . It is almost impossible now to obtain pure pheny-ethyl alcohol, so indispensable for the preparation of artificial otto of roses. Another primary material, benzaldehyde, is likewise exceedingly difficult to find in a pure form, free from chlorine. The commercial grades, containing appreciable amounts of chlorine, which are readily employed in the dyestuff industry, appear to be fairly abundant.

Analysis of Synthetic Drugs.

The attention of those interested in the analysis of artificial medicinals is directed to the following recent paper on:

Salvarsan and Neosalvarsan, M. J. Webster, Analyst, 1916, *41*, 231; Ann. Chim. anal., 1917, *22*, 37.

BOOK REVIEWS—Section VII

"Notes on Military Explosives"

By Erasmus M. Weaver, Brigadier General, U. S. Army; Chief of Coast Artillery. Fourth edition, enlarged and revised. 436 pages. Illustrations from drawings. Price, $3.25 net. New York, John Wiley & Sons, Inc. London, Chapman & Hall, Ltd.

Exhaustion of the third edition of this exceedingly comprehensive work has given the author an opportunity to bring it up to date and to include such changes bearing upon the manufacture, use, storage and transportation of military explosives as have been developed during the last four years. It has particularly given him the opportunity to treat of the changes which have developed since the outbreak of the European war, the more important of which have been the substitution of wood pulp for cotton in the manufacture of the nitrocellulose explosives and the fixation of the nitrogen of the air by three separate processes. The initial chapter on fundamental principles of chemistry is useful for reference. The chapter on substances used in the manufacture of explosives is particularly exhaustive, and discusses the roles played by the various constituents as well as their sources. Each class of explosives receives full attention, and there are also copious remarks on storage, handling, service tests, etc. Matter in the appendix includes the revised regulations of the Interstate Commerce Commission in regard to the transportation of explosives.

"How To Build Up Furnace Efficiency"

By Joseph W. Hays. Tenth edition, 158 pages. With numerous illustrations from photographs and diagrams. Price, $1.00. Chicago, Joseph W. Hays. Christiania, Samuel Eie. Dover, Dover Printing & Publishing Co., Ltd.

This chatty, non-technical little volume deals exhaustively with the subject of needless coal waste in power plants. The author, a well-known combustion engineer, again advances the claim that one-quarter of the coal purchased by the average power plant is wasted through causes which are preventable. In the present edition he endeavors to show just how and why fuel is wasted, and follows his analysis up with two chapters devoted to methods of locating and stopping wastes. A final chapter includes a great deal of sound advice on keeping the wastes stopped. With this edition the book reaches its fiftieth thousand, and a perusal of it clearly indicates the reason for its popularity. It is designed to interest readers with no technical training and it succeeds admirably in its purpose, while its simple, straight-from-the-shoulder style drives home the lessons which it teaches without a conscious mental effort on the part of the reader

DETERMINATION OF THE EXPLOSIBILITY OF PYRITES

And the Effect of this Quality Upon Its Available Sulphŭr and the Sulphur Contents of its Cinders

By C. R. Gyzander *

WHEN one buys pyrites as a source of sulphur for the manufacture of sulphuric acid, high contents of sulphur in the ore is not necessarily a guarantee of its fitness, since other characteristics have a bearing on the amount of sulphur available for the production of SO_2. So, for example, the explosive property of some varieties of pyrites, while rather an aid to high efficiency when the ore is burned as fines, is a great drawback when the ore is to be burned as lump ore, since the dust which the explosion of the ore causes, fills up the interstices between the lumps and thus prevents the free access of air, in consequence of which the combustion is incomplete, the resulting cinders high in sulphur, while the available sulphur is low.

Again, some ores consist of small crystals or particles of pyrites and sand or silica, loosely cemented together and readily broken up during the process of combustion, thus forming dust which may clog and render the ore unsuitable as a lump ore.

These two qualities are easily exhibited by heating a lump of the ore on a clay triangle over the naked flame of a Bunsen burner while a screen of fine netting is placed over the lump to prevent the scattering of the small pieces of ore if it does explode.

The quantitative determination of its explosibility or crumbling quality is accomplished by heating the ore in a covered dish at a high temperature, until crumbling or explosibility has ceased, then cooling, screening and weighing the ore, originally selected to remain on a certain size screen while passing through a next larger size.

Call the total weight of the burnt ore A grams while the portion that passes through the smaller screen is B; then the explosibility or crumbling of the ore is $\frac{B}{A}$ 100%.

By the use of graded sieves, the percentage of the various sizes resulting from the explosion may be determined.

Some authorities claim to destroy or minimize the explosive effect by a gradual preheating of the ore, but my own observations in this direction do not confirm that statement, possibly because the exact conditions of a successful preheating were unknown.

Twenty-four hours preheating at temperatures from 120 to 340°C (at which temperature explosibility seems to commence) has no apparent effect in diminishing the explosive quality.

Some users of ore have offered as an explanation for the explosibility of a pyrites that its mass is subject to an unequal internal strain, but the fact that preheating seems to have no effect in anealing or equalizing this strain, even up to temperatures at which it begins to explode, seems to argue against this theory.

Dr. Lunge suggests that the explosibility is due to pockets of CO_2 gas, the expansion of which, during the process of combustion, causes the breakage of the lump with more or less explosive violence.

The correctness of this view seems to be borne out by the fact that the explosibility diminishes as the ore is crushed down in size, a process which naturally would tend to destroy any existing pockets through cleavage.

If actual values with reference to explosibility are sought the ore should be heated in the same size that it is to be used in the burners, that is, a definite weight of ore should be graded by screening and each portion tested, separately, for explosibility.

But this would involve the use of a cumbrous laboratory apparatus, while a relative explosibility, that is, the explosibility of the ore of a uniform but small size, would be equally as valuable as a means of comparison of two grades of ore, while the laboratory apparatus would be more manageable.

For a comparative test therefore, the ore may be crushed to pass a 7/16 but remain on a 5/16 round hole screen, when, after heating, what passes through the 5/16 screen is explosive ore. This portion may now be graded to determine dust qualities.

As example of the application of this explosive test I quote the following cases:

The ore is Spanish "Perrunal" and Rio Tinto washed ore, of which 240 grams, crushed to pass a 7/16 but to remain on a 5/16 round hole screen, were heated in a covered agate wash bowl placed in a suitable ring tripod and heated with a large Meker

This goes to show what a wide difference the same kind of ore does exhibit as to explosibility and the same holds as to its cinder tests which, with the Perrunal ore, varies from less than 1% for a non-explosive ore up to 5 and 6% for explosive ore, while the Rio Tinto cinders vary from 4 to 10%, due to choking with dust, since these cinder tests refer to the ores burnt as lump ore.

Though these explosive tests do not give absolute figures, they indicate that one may reasonably look for a difference in the cinder values of such ores when burned as lump ore. What exact relation this relative explosion test bears to the cinder value is not known, since no systematic determinations have been carried out on separate lots, but whatever relation does exist, can only be of a local significance, since a lump burner with a large sectional area and shallow depth will be less affected by the dust than one of small sectional area and greater depth, for the chances are that the latter will retain more of the obstructive dust than the former. I think the appended figures may speak a word of advice to some one and thus be a profitable aid in helping him to judge of the fitness of the ore for use as a lump ore in the production of SO_2. It may be that the difference in the sulphur contents of the cinders of an explosive ore referred to burners of a certain construction, when compared with what should be the legitimate sulphur content of this ore if it were non-explosive, would more than pay for the cost of crushing the lump into fines, which is the most effective form in which an explosive ore could be handled.

That the size of the lump does cause a difference in the explosive test will be seen from the following figures, which were obtained with a specially selected explosive Perrunal ore.

LUMP, SIZE OF HEN'S EGGS.

Ore exploded	100.0%
of which	
On 5/16 round hole screen	16.23%

On 20 mesh sieve	4.76%
Through 20 mesh sieve	6.03%
	37.42%

CRUSHED TO PASS NO. 6 MESH AND REMAIN ON NO. 10 MESH SIEVE.

Ore exploded	7.71%
of which	
On 20 mesh sieve	6.33%
Through 20 mesh sieve	1.38%
	7.71%

Or the explosibility has dropped from 100 to 7.71% by varying the size of the lump from that of a hen's egg to that of the size of coarse fines.

But even though the ore is non-explosive or non-crumbling it still does not follow that it is economical as a source of sulphur, since its burning qualities may be poor; that is, the rate at which it gives up its sulphur, the rate of change of the ore, is low, or, as it is usually expressed, it burns more or less freely, and it is evident that, since the ore is subject to the process of burning, whatever it may be, for a definite length of time, the more freely burning ore will have less sulphur remaining unburnt in a given time than the ore that burns more slowly, if such a quality does exist as an adjunct to a lot of pyrites.

Experience has proved that it does, and therefore the determination of the rate of change of combustion and its application to the determination of available sulphur as well as the sulphur contents of the cinders, will now be described. .

The method, in brief, consists of burning a convenient amount of the ore, crushed to pass a 50 mesh sieve in a standard size dish, under standard conditions of temperature, for various intervals of time, and determining the amount of unburnt sulphur in the resultant cinders, which furnishes the data necessary for the calculation of the rate of change of the ore.

Since the combustion of pyrites, like most other chemical reactions, is influenced by temperature, it is absolutely necessary to have the analytical temperature conditions constant at all times. Further, the ore which is used as a standard for comparison should be a fines ore, or a non-explosive, non-crumbling lump ore, of which the sulphur value of its cinders is also known.

The manipulative details are as follows:

As a source of heat I use an electric furnace which attains a temperature of 1,000° F. and here I heat 2 grams of ore, crushed to pass a 50 mesh sieve and accurately weighed, in small, thin walled, electro-quartz dishes of uniform size and thickness. The ones I use hold 10 c.c. and have a thickness of wall of 1/32″.

Three of them are placed, close together, in a sheet iron rack with handle, the exact size of the furnace, having holes which fit the respective dishes, so that they touch the bottom of the oven when placed there. After 15-minute intervals of time, or longer if necessary, they are lifted, separately, out of the furnace with crucible tongs, while an empty dish takes its place in the furnace, so as to insure that the circulation of the heat remain as nearly as possible constant.

The reaction is stopped by placing 5 grams Na_2CO_3 on top of the dish as soon as it comes out of the furnace, and it is then left to cool.

There thus results three samples of cinders, having been exposed for known intervals of time, say for 15, 30 and 45 minutes respectively, and the sulphur contents of which is determined, by transferring each dish of cinders and Na_2CO_3 to a roomy platinum dish, breaking up the cake of cinders with a flattened, thick glass rod, adding 5 grams $NaNO_3$, mixing and fusing to oxidize the sulphur.

After cooling it is lixiviated with water, filtered, filtrate acidified with excess of HCl in covered glass dish, CO_2 boiled off, solution evaporated to dryness, the dry mass dissolved in water, acidified with HCl, filtered from SiO_2, precipitated by $BaCl_2$ and this, washed, dried, ignited, cooled and weighed, from which weights we ascertain its sulphur content, which corresponds to $a - x$ in the equation. Whether we regard the combustion of the pyrites merely as a distillation of its sulphur contents, or as an oxidation process, or both, the reaction may be treated as one of the first order, since, even in the case of the oxidation, both in the analytical and practical operation, the burning ore is continually being treated with fresh quantities of air, in consequence of which the oxygen phase of the reaction is constant and hence only the sulphur undergoing change. The rate of change is therefore expressed by the differential equation

$$(1) \quad \frac{dx}{dt} = K(a - x)$$

which when integrated for $x = O$ when $t = O$ becomes

$$(2) \quad \frac{1}{t} \log_e \frac{a}{a - x} = K$$

Here (a) represents the amount of sulphur in the 2 grams of ore used.

From equation 2 we see that, since the amount of action, or (x), in a given time (t), is proportional to (a), other conditions being constant, (m) times as much ore, or (ma) grams, would give (m) times as much action or (mx) in the time (t), hence the logarithmic factor of the equation becomes:

$$\frac{ma}{ma - mx} = \frac{m\,a}{m(a - x)} = \frac{a}{a - x} \text{ or constant}$$

Therefore the value of K is independent of the value of (a), and so we may use the constant quantity 2 grams of ore, even if they do not always carry the same amount of sulphur. The value of K is still proportional to the velocity of the reaction, if the temperature conditions are constant, or any other conditions that may have an influence on the reaction are constant, like size and thickness of dishes used for the combustion.

As a sample for comparison I use a non-explosive, non-crumbling variety of perrunal ore, which gave the following tests:

Sulphur in ore....................	50.5%
Sulphur in cinders................	1.0%

$$2 \text{ grams ore} = \frac{50.5}{100} \times 2 = 1.01 \text{ grams sulphur} = a$$

t	a — x	K_{10}
15	.27163	.03802
30	.06351	.04004
45	.01813	.03879

Average K_{10}....... .03895

K_{10} represents the value of the velocity constant when referred to common logarithms in equation 2. With reference to natural logs it is to be multiplied by 2.30259, hence $K_e = 2.30259$, $K_{10} = .089686$.

Since K is independent of the value of (a) we may refer it to 100 grams of ore when determining available sulphur and cinder sulphur, in preference to using 2 grams, or the analytical amount used in determining K.

The composition of the cinders is, in all probability, a mixture of Fe_2O_3 and Fe_3O_4, but we will assume them to be Fe_2O_3 as sufficiently correct for our purpose.

The next question is, then, how long will we have to burn 100 grams of the ore, under the same conditions of temperature and so on as prevailed wher determining K_e, in order that the cinders may contain 1% sulphur?

If to do this x grams of sulphur burn off, the cinders will be $100 - x + \frac{48}{128.24} x$, since for every 4 atoms of sulphur burnt off 3 atoms of oxygen are taken up to form Fe_2O_3, and we have the proportion

$$\left(100 - x + \frac{48x}{128.24}\right) : (50.5 - x) = 100 : 1$$

$x = 49.81\%$ available sulphur burnt off

$a - x = .69\%$ sulphur left in cinders

$a = 50.50$

Substituting these values in equation 2 we have, when using common logs:

$$\frac{2.30259}{t} \log \frac{50.5}{.69} = .089686$$

$$t = 48 \text{ minutes}$$

That is to say, 48 minutes is the time we must refer the burning of all ores, so long as their rate of change or the value of K_e has been determined in the electric furnace.

If for some reason this has to be given up, the value of K_e will have to be re-established for the new conditions, before we may make any computations as to cinder values or available sulphur.

Another lot of Perrunal ore tested as follows:

Sulphur in ore....................	49.3%
Sulphur in cinders................	2.3%

$$2 \text{ grams ore} = \frac{49.3}{100} \times 2 = .9860 = a$$

t	a-x	K_{10}
15	.37145	.02826
30	.10163	.03296
45	.02373	.03596

Average K_{10}.. .03239

$K_e = 2.30259 \qquad K_{10} = .07458$

100 grams of this ore, burning as above for 48 minutes would leave a-x sulphur for cinders and we have:

$$\frac{2.30259}{48} \log \frac{49.3}{a\text{-}x} = .074581$$

$a\text{-}x = 1.37$ grams sulphur left in cinders

$x = 47.93$ grams available sulphur

$A = 49.30$

$$100\text{-}47.93 + \frac{48}{128.24} \times 47.93 = 70.01 \text{ grams } Fe_2O_3$$

cinders

$$\frac{1.37}{70.01} \times 100 = 2.0\% \text{ sulphur in cinders}$$

Found = 2.3% sulphur in cinders

The above value of K_{10} is not in very good agreement as a constant, but the calculations show that it is near enough for this case. Had the sulphur value of the cinders been required before burning the ore it would have been a safer practice to repeat the analytical operation with a view to obtaining better agreeing values of K.

A sample of Eustis fines contained.

Sulphur in ore....................	42.98%
Sulphur in cinders................	2.70%

$$2 \text{ grams ore} = \frac{42.98}{100} \times 2 = .8596 = a$$

$K_e = 2.30259$ $K_{01} = .07652$

Burning 48 minutes to Fe_2O_3 cinders

$$\frac{2.30259}{48} \log \frac{43.24}{a\text{-}x} = .07652$$

Sulphur in cinders......... $a\text{-}x = 1.09\%$
Available sulphur......... $x = 42.15\%$

$$100-42.15 + \frac{48}{128.24} x\ 42.15 = 73.94 \text{ grams } Fe_2O_3 \text{ cinders}$$

$$\frac{1.09}{73.94} x\ 100 = 1.33\% \text{ sulphur in cinders.}$$

Found 4.10% sulphur in cinders

That is, burnt as fines the ore would have left only 1.33% sulphur in the cinders, but on account of the explosive dust and clogging this rose to 4.10%.

I will now append two more sets of determinations made in 1908.

In August of that year, Carridad lump ore was burned at one set of burners, giving high sluphur, while Eustis lump was being burned at another set of burners with the normal sulphur test in the cinders. As it happened that men with less experience were engaged on the burners where the Carridad ore was burned it was not unreasonable to suspect that the men, either from laziness or ignorance, had not given the proper attention to breaking and charging that they should, and so I tried the determination of the rate of change of the two ores, with the expectation that the suspicions regarding the men's guilt would be confirmed.

The results, however, entirely exonerated the men from all blame and showed the cause to be due to the poor burning quality of the ore itself. At that time I did not have the electric furnace, but made the determination in one and the same dish placed on a tripod and heated with a small Meker burner, shielded from draughts by a sheet iron hood.

The results were as follows:

EUSTIS LUMP ORE

Sulphur in ore..............45.8%
Sulphur in cinders........... 3.0%

$$2 \text{ grams ore} = \frac{45.8}{100} + 2 = .91.60 = a$$

t	a-x	K_{10}
15	.3705	.02620
30	.1893	.02282
45	.0446	.02916

Average K_{10} .02606

$_e = 2.30250$ $K_{10} = .06001$

$$(100 - x + \frac{48}{128.24} x) : (45.8 - x) = 100 : 3$$

$x = 43.62$ grams sulphur burnt off
$a - x = \;\;2.18$ grams sulphur in cinders

$a = 45.80$

$$\frac{2.30259}{t} \log \frac{45.8}{2.18} = .06001$$

$t = 51$ minutes

CARRIDAD ORE

Sulphur in ore.............. 43.7%
Sulphur in cinders..........9.70%

$$2 \text{ grams or} = \frac{43.7}{100} \times 2 = .8740 = a$$

t	a-x	K_{10}
15	.5027	.01601
30	.3243	.01435
45	.1945	.01450

Average K_{10} .01495

$K_e = 2.30259$ $K_{10} = .03442$

$$\frac{2.30259}{51} \log \frac{43.7}{a-x} = .03442$$

$a - x = \;\;7.55$ grams sulphur left in cinders
$x = 36.15$ " " burnt off

$a = 43.70$

$$100 - 36.15 + \frac{48}{128.24} \times 36.15 = 76.91 \text{ grams cinder}$$

$$\frac{7.55}{76.91} \times 100 = 9.80\% \text{ sulphur in cinders}$$

Found = 9.70% sulphur in cinders

Again, in November of that same year, some of this Carridad ore was burned as fines with such unusual low sulphur test in the cinders, compared with the lump ore, that now the suspicion arose as to the accuracy of the cinder samples or the cinder test.

Again the determination of the rate of change of the fines ore exonerated the parties concerned, and placed the explanation on the better burning qualities of the fines ore.

As there was not any surety that the flame could be adjusted to the exact conditions prevailing when the test of the lump ores was made the preceding August, I chose for comparison a sample of Eustis fines ore burned the same month as the Carridad fines.

The results were as follows:

EUSTIS FINES ORE.

Sulphur in ore.................... 46.1%
Sulphur in cinders................ 2.6%

$$2 \text{ grams ore} = \frac{46.1}{100} \times 2 = .9220 = a$$

t	a-x	K_{10}
15	.3962	.0247
30	.2120	.0214
45	.0675	.0253

Average K_{10} .0238

$K_e = 2.30259$ $K_{10} = .0548$

$$(100 - x + \frac{48}{128.24} x) : (46.1 - x) = 100 : 2.6$$

$x = 44.22$ grams sulphur burnt off
$a - x = \;\;1.88$ grams sulphur left in cinders

$a \quad = 46.10$

$$\frac{2.30259}{t} \log \frac{46.1}{1.88} = .0548$$

$t = 58$ minutes

CARRIDAD FINES.

Sulphur in ore..................... 42.2%
Sulphur in cinders................ 2.1%

$$2 \text{ grams ore} = \frac{42.2}{100} \times 2 = .8440 \text{ grams} = a$$

t	a-x	K_{10}
15	.3628	.0245
30	.1941	.0213
45	.0621	.0252

Average K_{10} .0236

$K_e = 2.30259$ $K_{10} = .0543$

$$\frac{2.30259}{58} \log \frac{42.2}{a-x} = .0543$$

$a - x = \;\;1.80\%$ sulphur left in cinders
$x = 40.40\%$ sulphur burnt off

$a \quad = 42.20$

$$100 - 40.4 + \frac{48}{128.24} \times 40.4 = 74.72 \text{ grams cinders}$$

$$\frac{1.80}{74.72} \times 100 = 2.40\% \text{ sulphur in cinders}$$

Found 2.10% sulphur in cinders

It is well known that as regards available sulphur in pyrites no method has hitherto been presented that agrees at all with practice.

To account for the low yield of available sulphur it is the custom, in some places at least, to determine such heavy metals as lead, copper and zinc and deduct from the total sulphur that equivalent to sulphates of these metals, but even so, there is usually no agreement with practical yields, and as the sulphates of these heavy metals are all decomposable at a bright red heat, the temperature of the burners.

it is evident that such a practice is faulty, even if it occasionally should seem to agree with practical results.

The only reliable method of arriving at the available sulphur content of a pyrites is, as has been shown, the determination of the rate of change of the ore, compared with some other ore that works normally and the available sulphur of which is known..

Furthermore, this determination serves as a check upon results already obtained and so helps to place the true explanation upon them instead of subjecting them to mere suspicions, which, though seemingly reasonable, may still be untrue.

PROGRAM FOR THIRD CHEMICAL EXPOSITION IS NEARING COMPLETION

All things indicate that the Third National Exposition of Chemical Industries at the Grand Central Palace, New York, during the week of Sept. 24th, will far outstrip its predecessors in magnitude and general interest.

At the last exposition two floors of the big building were occupied by the 187 exhibitors, while this year three floors, possibly more, will be occupied. Already the list of exhibitors contains 250 names of companies engaged in practically every field of industry.

The program now forming shows that on Wednesday. Sept. 26th, the Technical Association of Pulp and Paper Industry will meet at the exposition. On Thursday evening the American Institute of Chemical Engineers will meet, and Friday evening has been set aside for the American Chemical Society's New York Section.

Opening addresses will be made on that occasion Monday, Sept. 24th, at 2 p. m., by Dr. Charles H. Herty, chairman of the Advisory Committee of the exposition, and editor of the Journal of Industrial and Engineering Chemistry. Prof. James Stieglitz, president of the American Chemical Society; Dr. Colin G. Fink, president of the American Electrochemical Society, and Dr. G. W. Thompson, president of the American Institute of Chemical Engineers, will also address those present on the opening day.

Among other speakers on the program for other days are Mr. W. S. Kies, vice-president of the National City Bank, New York, who will speak on "The Development of Export Trade with South America"; Prof. Marston Taylor Bogert, chairman of the Chemistry Committee, National Research Council, who will speak on "The Operation and Work of the National Research Council for the National Weal," and Dr. Leo H. Baekeland, of the Naval Consulting Board, who will have for his topic "The Future of American Chemical Industry."

One day has been set aside for discussing a symposium of our national resources as opportunities for chemical industries, and among the speakers will be: Mr. C. H. Crawford, assistant to the president of the Nashville, Chattanooga & St. Louis Ry.; Dr. Y. V. Kelsey, chemist and industrial agent for the Carolina, Clinchfield & Ohio Ry.; Dr. E. A. Schubert, mineralogist-geologist, Norfolk & Western Ry.; and Dr. T. P. Maynard, mineralogist-geologist, Central of Georgia Ry. and Atlantic Coast Line Ry.

The motion picture program will be one of wide interest. The American Cyanamid Co. and the General Electric Co. have already arranged to exhibit their films, while the Bureau of Commercial Economics at Washington will also supply many toward completing the range of industrial films.

A NEW PROCESS FOR THE PRODUCTION OF PHTHALIC ACID AND ITS ANHYDRIDE

The United States Department of Agriculture announces that the Color Investigation Laboratory of the Bureau of Chemistry, of this department, has perfected, on a laboratory scale, a new process for the manufacture of phthalic acid and phthalic anhydride. This process, as carried out in the laboratories, appears so promising that it is thought that some manufacturers of chemicals and dyestuffs in this country may be able to supply their demands for these compounds by this process, provided the process can be reproduced upon a technical scale so as to obtain results commensurate with the laboratory investigations.

With a view to helping the chemical industry of this country, the Department of Agriculture hereby announces that it is ready to assist manufacturers who wish to produce these compounds. The expenses of the technical installation and of the labor and materials necessary will of necessity be borne by the firm, individual, or corporation wishing to manufacture the products. The chemists of the Color Investigation Laboratory will assist with expert advice, etc. The department reserves the right to publish all the data obtained from the technical experiments.

Since it seems very desirable that phthalic acid and phthalic anhydride be made available in large quantity in this country at the earliest possible moment. this offer of assistance will not be held open by the department for an indefinite period.

George H. Segal Co. to Build New Plant.

A new chemical manufacturing plant will be established on Meadow Street, Kearney meadow section, Newark, N. J., by George H. Segal Co., 95 William St., New York City.

ULTRA VIOLET LIGHT

Its Application in Chemical Arts

By Carleton Ellis and A. A. Wells.[*]

This Is the Fifth Installment of an Article Dealing with Investigations Conducted by the Writers Into the Possible Application of Ultra Violet Light. The Present Installment Discusses the Work of Other Investigators in Connection with the Effectiveness of Its Rays for the Sterilization of Transparent and Opaque Liquids, Emulsions, Fats, Etc.; Their Efficiency as Compared with Ozone, and the Cost of Municipal Water Sterilization by Ultra Violet Light. Part VI. Will Appear in the Next Issue.

PART V

Sterilization of Liquids.

THE application of ultra violet rays to the sterilization of liquids, such as water or milk, has been the subject of numerous investigations and a considerable number of patents have been issued for processes of sterilization and for apparatus suitable for carrying out the sterilization of liquids on an industrial scale, by means of ultra violet light.

According to *von Recklinghausen* (Journal, Franklin Institute, 1914, 681) practically every source of light produces, together with visible light rays, some of the wave lengths shorter than those which are perceptible to the human eye. The shortest wave length which the human eye is capable of receiving is about .3969 μ, but it is claimed that certain eye structures have been able to preserve light rays somewhat shorter than this.

One of the typical characteristics of ultra violet light rays shorter than .3969 μ is its bactericidal or sterilizing power. That the longer light rays do not sterilize to any material extent is probably due to the fact that living beings have the power to accustom themselves to the conditions under which they must live and inasmuch as these longer light waves are received from the sun, living creatures have fortified themselves against their action.

A great deal of our knowledge of the sterilizing effect of ultra violet light is due to *Ward*, who first analyzed the biologic effect of the light spectrum by exposing an affected agar plate to the entire range of the solar spectrum with the result that colonies grew quite rapidly at the red, while at the blue or ultra violet end no colonies were formed.

These tests were made in vacuo as well as in the air, with practically the same results. Ward also sterilized water of the Thames, by exposing it to ultra violet light.

Finsen and his pupils did a large amount of work on sterilization and one of the pupils first proposed the use of the ultra violet light for the sterilization of milk as well as other liquids. Finsen's researches did not meet with any immediate technical application probably due to the source of light which he was compelled to use, as the mercury quartz lamp did not exist at that time.

In the sterilization of water, von Recklinghausen states that usually a small part of a second (about 1/20) is sufficient to cause the death of microbes in case they can be exposed close enough to the source of light. The sterilizing power of ultra violet light is inversely proportional to the distance between the light and the material to be sterilized. In sterilization by means of heat it is well recognized that certain spores and bacteria have different degrees of resistivity and this especially is true in the case of spores, which can be heated to a relatively high temperature without being killed. It has been found, however, that these organisms do not have a wide range of resistance but that a comparatively short exposure is sufficient to kill the most hardy.

For instance, certain spores twenty times as resistant to chemicals as were unprotected forms of germs were destroyed by about three times as much exposure to ultra violet light. In other words, the resistance of these two classes of bacteria is practically the same. The accompanying diagram shows the length of time necessary to efficiently sterilize clear water when inoculated with a variety of germs and spores. *(See Fig. 1, p. 189)*. It has been claimed by some writers that the sterilizing effect of ultra violet light is due to the small amount of hydrogen peroxide which is formed on the exposure of water to the ultra violet rays. Von Recklinghausen states, however, that the amount of peroxide formed is so minute as to be sarcely perceptible even after an exposure of the water for ten or twelve hours. The amount generated during the brief exposure necessary to effectively sterilize with ultra violt light would be not more than about one-fifteen thousandth of the amount which would be necessary to act efficiently as a disinfectant.

Another interesting observation of von Recklinghausen is that while the temperature of the lamp itself has marked influence upon rapidity with which water may be sterilized, on the other hand the temperature of the water itself (provided all turbidity is removed) has very little if any effect upon the rate of sterilization. A perfectly clear and transparent piece of ice, having no bubbles or cloudiness will be sterilized as rapidly as an equal volume of water when exposed to light under the same conditions.

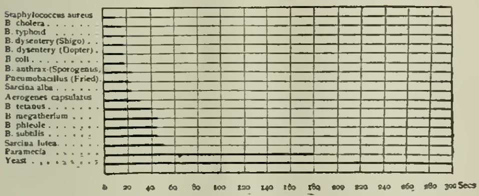
---

[*] All rights of publication in book form reserved by the authors, Consulting Chemists and Chemical Engineers, 92-98 Greenwood Ave., Montclair, N. J.

It is customary in some cases to describe the power of the ultra violet light in candle power, but this method, according to von Recklinghausen, is not a true standard by which to judge a lamp which is to be used for sterilization. The eye is insensible to ultra violet rays and consequently some other method of determining its strength must be devised. Von Recklinghausen states that the only true way of defining these rays would be by the analysis of the spectrum and determining the energy sent out by every wave length in the ultra violet position. This method, however, is very inconvenient. It is not possible in ordinary practice to work with only ultra violet rays. All the rays which come from the lamp must be taken into consideration and their effect noted. According to von Recklinghausen there is no method of sterilization which will cut out all light rays and allow all ultra violet rays to pass. Consequently the working conditions of a lamp are governed by all wave lengths given off. Water is practically as transparent as air to the ultra violet rays, provided there is no coloration or suspended matter which will interfere with the passage of the light rays. It is somewhat difficult, however, to determine when water is entirely free from very finely divided suspended matter which may act as a screen to the light or throw shadows in which bacteria may hide and not become exposed to the action of the rays. In order to eliminate this difficulty, von Recklinghausen suggests that the water be circulated in passing the lamps, in order that all sides of these somewhat small particles may be exposed and sterilization therefore be complete. In the ordinary sterilization of water, however, it is not necessary that the bactericidal content be reduced to zero, it being sufficient to give the light such treatment as will sufficiently remove all pathogenic bacteria. A very short exposure is sufficient to accomplish this result, in case the water is free from suspended particles. Water which is to be sterilized for surgical purposes, however, is treated for a longer period. Von Recklinghausen states that no difficulties are experienced in obtaining water which is sterile enough for surgical operations.

Fig. 1.

Seconds Necessary to Kill Different Types of Germs at 200 mm. from a Quartz Lamp Burning at 66 Volts, 3.5 Amperes.



Inasmuch as the rapidity and efficiency of the operation depends to a large extent upon the transparency of the liquid to be sterilized one would expect great difficulties in the sterilization of opaque substances such as milk. Von Recklinghausen states that many attempts have been made to sterilize milk, some of which were only partially successful due to the thickness of the layers exposed. He further states, however, that it is perfectly feasible to cause excellent sterilization of these bodies in case they are spread out thin enough and the milk is treated when fresh. The reason for the milk being more readily sterilized when fresh is due to the fact that young colonies of microbes or bacteria are more readily destroyed than older ones. Thus, as the milk stands, the bacteria colonies become older and consequently more resistant to the effects of the ultra violet light. It is also of interest to note that not only are bacteria destroyed by the action of the ultra violet rays, but according to von Recklinghausen, toxins are destroyed rapidly. The value of the ultra violet light in therapeutically treating certain diseases, such as tuberculosis, is considered by von Recklinghausen to be due to the fact that as the blood flows near the surface it is exposed to the action of the light rays and the toxins are killed. Thus, by giving long enough exposure it would be expected that a large portion of the blood would pass the blood vessels close to the skin and be purified.

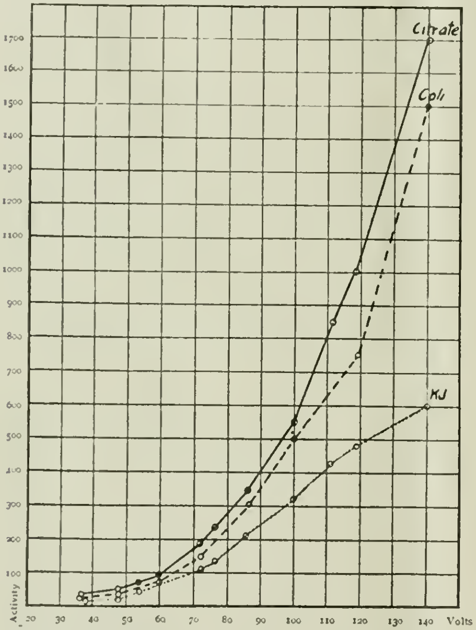
As the amount of ultra violet rays given out by a mercury vapor lamp depends to a greater or less extent upon the temperature at which the lamp is working, it is advisable in the sterilization of water, not to allow the water to touch the tube itself, as this would lower the temperature and therefore cut down the production of the short wave lengths. Von Recklinghausen observes that a physically perfect water will require very little illumination for complete sterilization, but due to the fact that it is almost impossible to commercially procure a water which is physically perfect, it is desirable, according to von Recklinghausen, to give the water several exposures, either by letting it pass the same lamp two or three times by a series of operations or by running it past several lamps. A rough and ready way of determining whether a water is sufficiently clear for rapid sterilization may be carried out by observing the sample under a strong light, against a dark background, when particles which are large enough to obstruct the light waves or hide bacteria will be revealed. (*See Fig.* 2)

In the Journal of the New England Water Works Association, 1914, 202, von Recklinghausen discusses the conditions under which water is best sterilized by ultra violet rays. The water should be free from suspended particles which cast a shadow, in which the bacteria would be shielded from the action of the rays. Coloring matter in small quantities and a small amount of colloidal material are stated by him not to be a serious drawback to sterilization, especially if the water be agitated when passing the lamps. Ice, if hard and clear, does not interfere. The lamp should be run at such a voltage as to maintain a temperature of about

700°C., when it will emit light which is rich in short rays. The lamp should be spaced away from the water so that the latter will not have a cooling effect on the lamp. The type of lamp known as the pistol lamp is the most efficient, about 90 per cent. of the rays being effective. Experiments show that 99.97 per cent. of the bacteria have been killed in filtered water by the action of the ultra violet rays and it is probable that the remaining .03 per cent. escaped because they were protected by floating particles in the water. About 100 kilowatt hours of current are required to sterilize a million gallons of water. As it is impossible to overdose water when sterilizing by this method a large factor of safety may be used. This is not possible when chemicals are used, otherwise the water will have a bad flavor. With current at one-tenth cent per kilowatt hour, the cost of sterilizing water is stated to run from ten to thirty cents per million gallons including upkeep of lamps.

Fig. 2.

Comparative measure of ultra violet activity of 220 volt quartz lamp burning at different voltages by three methods: (a) Decomposition of citrate of silver; (b) decomposition of potassium iodide; (c) annihilation of bacterium coli.



Cost of Operation.

Von Recklinghausen (Elec. World, 62, 181) further states that water can be economically sterilized by ultra violet rays, if it is free from suspended matter. A large quartz tube mercury vapor lamp for this use has been developed. The tube is made of the pistol type; the ends being held in a clamp and the whole tube pushed into a quartz cylinder which projects into the chamber containing the water to be sterilized. This allows practically all the rays from the lamp to enter the water. The largest type of these lamps in service is used on a 500-volt circuit, taking about 3 amperes and 375 volts. The ultra violet production of these lamps is almost 50 times as great as that of an ordinary 110-volt, 3.5 ampere lamp. (Power ratio = 4:1). This result is probably due to the mutual heating effect of the two branches of the tube. For sterilizing 500—2000 tons of water per 24 hours, 1 or 2 lamps are required. For more water, a multiple unit is used, i.e. several lamps in a canal through which the water flows. Such a canal has been in continuous operation in a municipal water plant in Europe for 8 months, treating 7,500—8,000 tons of filtered river water per day. The apparatus is very simple and requires scarcely any attendance.

Efficiency of Ultra Violet Light Compared With Ozone.

Von Recklinghausen notes that (Proc. Am. Inst. Elec. Eng. 33, 1906, 1914; Chem. Abs. 1915, 494) the inverse square law holds true in the case of ultra violet rays used for sterilization if correction is made for the line shape of the source and for some absorption in the air. Water as it comes from a mechanical filter may be treated at a total cost of $0.60 per million gallons. While chemical treatment may be somewhat cheaper, considering the expert attention required, any increased cost would be offset by a cleaner, chemical-free water. Typhoid records from certain European towns show a total absence of this disease since ultra violet sterilization was introduced. Regarding competition with ozone, a comparative test run at Genoa for six months showed an equal cost for power, but a higher first cost and operation cost for the ozone equipment.

Effect of Agitation.

Another process for sterilizing liquids disclosed by von Recklinghausen, (J. S. C. I., 1915, 1223; U. S. Patent 1,156,947, October 19, 1915) involves an apparatus by means of which water or other liquid to be sterilized flows in comparatively thin films past the lamp and at certain different points, this effect being obtained by placing within the treating vessel a number of baffle plates and forcing the water to pass over one baffle and under the next and so on. By this method the water is passed by the lamp any desired number of times, as well as being agitated, which allows the action of the rays to become effective in liquids containing small particles in suspension because of the fact that these small particles are rotated and light strikes all sides of them.

Mineral Deposits on Lamp.

Henri, Helbronner and *von Recklinghausen* (U. S. Patent 1,200,940, Oct. 19, 1910) state that when water is being sterilized, deposits of mineral matter similar to boiler crust, form on the lamp tube, thereby interfering with the passage of the ultra violet rays. In order to obviate this, they propose to construct an apparatus in which the water circulates around the protecting tube of the lamp, thereby keeping it clean. Another advantage of this apparatus is that the water is agitated in its passage and is brought in close contact with the lamp, causing effective sterilization.

Sterilization of Opaque Liquids.

In another process for treating liquids with ultra violet light, Henri, Helbronner and von Recklinghausen, (U. S. Patent 1,140,818, May 25, 1915) state that in sterilizing opaque or highly colored liquids such as milk, wine and so forth, it is undesirable to have the liquids exposed to the atmposhere while undergoing the sterilization process. In apparatus which they describe, the liquid to be treated is passed through a shallow chamber which is provided with a cover of some substance such as quartz which is transparent to ultra violet rays. The lamp is placed in such a manner that the rays may reach all parts of the container and thus become efficient for the treatment of the liquid contained in the chamber. In one instance the treating chamber is circular in cross section, the liquids to be treated being allowed to flow along the sides in a thin film. Provision is also made for cooling the apparatus.

The Investigations of Parkinson.

Parkinson (Thirty-third Annual Report of Provincial Board of Health of Ontario, Canada, 1914, page 156) has made a thorough research on the sterilization of water by means of ultra violet light.

The source of water used by Parkinson is the Great Lakes, which he states is very satisfactory for use during the greater part of the year but in case of storms the water becomes turbid and is quite highly infected. Purification by filtration and chemical treatment therefore becomes necessary in order to insure at all times a pure drinking water. Owing to the purity of the water as it came from the purification plants it was necessary for Parkinson to pollute the water in order to have the bacteria count high enough for accurate results. Two types of apparatus were used by Parkinson, one being a small form having a 110-volt lamp, the other a larger apparatus having a 500-volt lamp In both cases the apparatus was of the gravity type. In the smaller apparatus the lamp was suspended over the water, while in the larger one the lamp was entirely surrounded by the water during sterilization. Both pieces of apparatus were supplied with baffles, which were movable so that they could be shifted from one place to another or be removed entirely. After a long series of experiments with the baffles in various places and removed altogther, Parkinson concludes that baffles are not necessarily in apparatus for the sterilization of water and that sterilization takes place almost immediately when the water comes in contact with the rays from the lamp. He states, however, that by using baffles a safety factor is obtained which makes sterilization a little more sure. When using ultra violet light for the sterilization of water, it is impossible to impart an undesirable flavor to the water by over-treatment, consequently the only drawback to long treatment is the additional expense. In the location of apparatus for treating water Parkinson states that he had some difficulty from dust being deposited around the lamp, which caused its efficiency to be decreased. In order to obviate this, the sterilizing apparatus should be placed in some locality which is as free from dust as possible and it may prove advantageous to enclose the apparatus entirely in some special form of housing. In regard to the effect of slight turbidity on the sterilization of water, when treated with ultra violet light, Parkinson concludes that a small amount of turbidity is not detrimental, but in case turbidity is present the treatment with light must be slightly prolonged and the water should be agitated. Gross particles, however, should be avoided, inasmuch as they serve as a hindrance to the penetration of the light and perhaps throw shadows in which the bacteria are shielded from the light rays. When treating water with ultra violet rays, Parkinson states that one noticeable feature is that the quality of the water so sterilized is very constant. There are no jumps of the bacteria count and in case the sterilizing apparatus is working steadily the bacteria count should remain practically constant, provided of course, the operating conditions, such as flow of water, voltage of lamp, etc., are maintained constant. Various tables are given in which the details of various experiments are collected, and conclusions are drawn from these tables.

TABLE I.

Adjustment of Baffles.

Date.	Horizontal Baffles.	Opening in the Inclined Baffles.	Turbidity. Parts per Million	Voltage.	Percentage Bacterial Removal. 18-22° C. Count.	37.5° C. Count.
Dec. 24	In place	¼ inch	1	350	99.84	98.7
Dec. 24	In place	½ inch	1	350	99.3	99.2
Dec. 24	In place	1 inch	1	350	99.8	99.67
Dec. 24	In place	1½ inch	1	350	99.8	99.7
Dec. 24	In place	2½ inch	1	350	99.84	99.72
Dec. 26	Removed	¼ inch	30	350	97.5	98.5
Dec. 26	Removed	½ inch	20	350	97.5	98.4
Dec. 26	Removed	¾ inch	1	350	99.6	99.9
Dec. 26	Removed	1 inch	20	350	98.7	99.0
Dec. 26	Removed	1½ inch	30	350	98.5	98.6
Dec. 26	Removed	2 inch	20	350	99.4	99.4

The following data from Parkinson's report illustrate concisely his conclusions in regard to several points which apparently are not definitely settled in the minds of various investigators:

Table 1 illustrates the effect of the baffling system on the sterilizing apparatus used, together with the results obtained on removing the baffles. It will be noted from this table that there is no great variation in the bacteria content when using the greatest baffling effect possible and also the least with the apparatus at hand, although there is a high bacteria count at the intermediate stage which is probably due to some outside source.

TABLE 2.

Progress of Sterilization in "D. F." Tank.

Sample Point.	Average Bacterial Count 18-22° C. Count.	Average Bacterial Count 37.5° C. Count.	Average Bacterial Count *Colon Fermentation.	Percentage Removal 18-22° C. Count.	Percentage Removal 37.5° C. Count.	Percentage Removal Colon Fermentation.	Percentage Removal Average Removal.
Influent	730	200	1,230				
A	50	17.4	31	93.2	91.3	97.5	94.0
B	49.5	12.7	29	93.4	93.6	97.6	94.8
C	23	4.2	29	96.9	96.9	97.6	98.1
Effluent	26	16.4	20	96.4	96.8	98.4	97.2

*B. coli per 100 cc. presumptive tests.

In Table 2 Parkinson gives the results of data of an instructive character as to the length of time necessary to cause sterilization. The samples taken at the various points are as follows:

A indicates a point just below the first baffle. B indicates a sample taken about midway between a set of baffles. C indicates a point close to the lamp just before the water passes out into the overflow. It will be noted from this table that there is almost complete bacterial removal when the water first comes in contact with the light.

TABLE 3.

Effect of Turbidity on the Rate of Sterilization.

Rate of Flow in Gallons per Hour.	Number of Samples.	Turbidity Parts per Million.	Voltage.	Percentage Bacterial Removal 18-22° C. Count.	Percentage Bacterial Removal 37.5° C. Count.	Percentage Bacterial Removal Colon Fermentation.
3,000	40	under 1	350	99.81	99.82	99.88
	20	30	350	99.4	98.5	
5,000	65	under 1	350	97	94	97.4
5,000	20	40	350	94.9	91.3	99.46
5,000	20	under 1	325	87.5	75	96.3
7,000	74	under 1	350	86.8	94.4	96.0
7,000	20	10	350	91.8	86.4	97

Table 3 shows the results of Parkinson's experiments upon the effect of turbidity, within certain limits, on the rate of sterilization. A large number of samples were used in each instance and conditions as to flow and voltage of lamp kept as near constant as possible. It will be noted from this table that there is practically no difference in the bacteria count at a given slow rate of speed in the turbid water and in that which is practically clear. Where high velocities were used, however, it will be noted that there is a difference in the bacteria count, depending upon the increase in turbidity and the increase in rate of flow, but a greater variation than this is caused by a change in the voltage of the lamp.

The details of the method of operating the lamp, of taking the bacteria count and of adding the definite contamination to the water supply are given in full.

Effect of Cooling Lamp Electrodes.

Thompson, (English Pat. 28,757, December 20, 1911) states that for the purpose of sterilizing water and other liquids it is preferable to keep the vapor pressure in the mercury lamp employed as low as possible; hence the electrode-containing cells must be efficiently cooled. On the other hand in order to avoid undesirable contact between the quartz globe of the lamp and the liquid, a quartz jacket is employed and the interspace is exhausted. In the lamp described, the quartz jacket does not extend to the electrode-containing cells at the end of the lamp, but is connected to the illuminating tube between the cells. The electrodes are thus kept cool by the liquid being sterilized or in case this is warm, by some external means, thus keeping the vapor pressure of the mercury low.

Effect of Peaty Waters.

Grimm and *Weldert* (Mitt. K. Pruf. Anst. f. Wasserversorg. u. Abwasserveseit. 1911, 14, 85; Chem. Zentr. 1911, 1, 1454) experimented with a mercury vapor lamp of 1,200 candle power and closed in a double walled quartz vessel, through which water was passed. Clear water containing less than 100 bacteria per cubic centimeter could be sterilized when passed through the apparatus at a velocity of 0.55 cubic meters per hour, but with water very rich in bacteria, sterilization was effected only when the velocity did not exceed 0.45 cubic meters per hour. Turbidity and the yellow coloration due to colloids, such as is observed in peaty waters, destroy the efficiency of the treatment for practical purposes. The cost of the treatment is stated to be very high compared with that of existing processes.

Swimming Pools.

The water of swimming pools can be purified by being passed rapidly through a filter and then subjected to the action of the ultra violet light (Scientific American, Aug. 15, 1914, 120). Tests have shown that all bacteria of intestinal origin are destroyed and the same water may be used over and over for weeks or even months.

U. S. Public Health Report.

A result of a study of the conditions on steam vessels engaged in interstate commerce in the sanitary district of the Great Lakes, is reported by *Cobb, Williams* and *Letton* (U. S. Pub. Health Rept. 31, 2845-67). The types of purification apparatus in use on the vessels of the Great Lakes are at present inefficient in maintaining the standards of purity prescribed by the U. S. Treasury Department. Three methods of purification are recommended; automatically operated water stills; injection of steam during the pumping of the water; and the use of ultra violet sterilizers. There is no other method recognized that under all circumstances will produce a water meeting the Government requirements.

The Oscillating Spark.

Kowalski (Elec. Rev. West. Elec. 66, 1055-6, 1915) states that the oscillating spark was found to be a more economical source of ultra violet light than the quartz enclosed mercury vapor lamp. Water sterilization requires but 45-90 watt hours per 1,000 gallons. To increase the amplitude, the capacity of the oscillating circuit must be as great and the inductions as small as possible. Electrode material and frequency of sparking determine the ultra violet radiation. The intensity from a 22 millimeter gap between invar electrodes is proportional to 2, 1.6, 1.3 and 1.0 with 20, 30, 40 and 50 sparks per second. The percentage distribution of radiation horizontally in the direction of the axis of a 110-volt Heraeus lamp at 90 volts and 3.1 amperes was: heat 24%, visible rays 41%, ultra violet rays 35%. From 22 millimeter gap between invar electrodes at 30 sparks per second with 50.5 amperes in oscillating circuit: heat 22%, visible rays 18.6, ultra violet 59.4%. Oscillating sparks show 70% greater ultra violet radiation. For water sterilization the spark may be produced directly in water without a quartz envelope, which means an additional saving.

Effect of Colloids.

Courmont (Chem. Zeit., 1911, 35, 806; J.S.C.I., 1911, 1027) discusses the remarkable sterilizing power of the ultra violet light from a quartz mercury vapor lamp. For sterilizing water, which is comparatively transparent to the radiation, it is sufficient to place the lamp in the axis of a cylindrical vessel 60 cm. in diameter. Liquids containing colloids (wine, beer, peptone solution, etc.) absorb the ultra violet rays rapidly, and therefore sterilization is limited to the surface layer. For greatest efficiency, therefore, the water to be sterilized should be as clear as possible. Courmont also states that the action of sterilization is in no way connected with ozone or hydrogen peroxide formation.

Although malt liquors cannot well be sterilized by means of the mercury lamp, according to *Rolle*, (Woch. Brau, 1911, 28, 533, J.S.C.I., 1911, 1330), owing to their opacity to ultra violet rays, clear water can be completely sterilized almost instantaneously. *Rogier* has devised an apparatus for this purpose, which can be fitted to a water tap. It consists of a cylindrical mercury lamp, 30 cm. long, enclosed in quartz, and fixed in the axis of an aluminum tube 10 cm. wide, constructed near one end so that the water, in passing through, is brought very close to the lamp. The apparatus requires a current of 6 amperes at 30 volts, and is stated to produce per hour, 1,000-1,500 litres (200-300 gals.) of absolutely sterile water which can be used for drinking with perfect safety. A plant installed at Marseilles for sterilizing the drinking water by ultra violet rays, requires an expenditure of 12,000 kilowatt hours per 100,000 cubic metres (220,000,000 gals.) at a cost of 0.24d. per cubic metre (1.1d. per 1,000 gals.). A large waterworks with its own electric plant could, however, reduce this cost to 0.45d per 1,000 gals., which is cheaper than sterilization by means of ozone and the apparatus required is much simpler and less costly.

Effect of Air Bubbles.

Von Recklinghausen (J.S.C.I., 1915, 1223; U. S. patent 1,156,948, October 19, 1915) claims that aside from particles in suspension, which cause turbidity, the greatest source of incomplete sterilization is caused by minute air bubles which throw shadows of sufficient density to shield the bacteria from the ultra violet rays. In apparatus described by von Recklinghausen it is claimed that this effect is practically overcome by forcing the water through a chamber in which there is a straight or unimpeded path, thereby avoiding the formation of air bubbles.

Emulsions Containing Bacteria.

Cernovodeanu and *Henri* (Comptes. rend., 1910, 150, 52) have tested the action of the ultra violet rays emitted by mercury lamps, on a variety of bacteria in emulsions containing from 10,000 to 100,000 per cubic centimeter. The bactericidal action of the ultra violet rays decreased more quickly than the square of the distance of the source from the bacteria. A 220-volt Cooper Hewitt lamp is five times as active as a 100-volt lamp when close to the bacteria and relatively far more active when further away. The bactericidal action is slightly greater when the layer of emulsion is thicker. Variations in temperature from 0° to 55°C. have no effect, and destruction of the bacteria is as rapid in the absence of oxygen as in the air. An emulsion made with water previously exposed to the rays is not more sensitive and the bactericidal action is not accelerated by the presence of traces of hydrogen peroxide. Different species of bacteria vary in their resistive power; whereas bacillus coli is killed in 15-20 seconds, bacillus subtilis requires 30-60 seconds . The most destructive of the ultra violet rays are those possessing a wave length above 2,800 Angstrom units. Protoplasm absorbs ultra violet rays of wave length above 2,900; accordingly it is the rays absorbed by the cell protoplasm which have the bactericidal action.

Sterilization of Milk.

Bloxham and *Ahrndsen* (Eng. Pat. 12,333, May 22, 1911) have proposed the following process of sterilization. The liquid, such as milk, is frozen into blocks or plates which are then exposed to the action of ultra violet rays. As the blocks thaw, a thin film of liquid is formed which is sufficiently transparent to enable it to be sterilized thoroughly by the rays.

Ayers and *Johnson* (Centr. Bakt. Parasitenk, Abt. II, 40, 109-13, 1914) have shown that ultra violet rays may markedly reduce the bacterial content of milk, but that they have no effect on vegetative cells. This method of sterilizing milk could not replace pasteurization because there would be no assurance of the destruction of pathogenic bacteria. Ultra violet rays impart to milk a disagreeable odor and taste which would render it unsalable.

Helbronner and von Recklinghausen, (U. S. patent 1,141,056, May 25, 1915) in sterilizing certain opaque liquids such as milk, in which it is necessary for efficient treatment that very thin films be obtained, note that complete sterilization by means of ultra violet light alone is quite difficult and that the prolonged treatment necessary is quite likely to have deleterious effects upon the flavor and digestive qualities of the liquid. They therefore propose to use a combination of heat sterilization together with ultra violet light. It is stated that when milk is given a short heat treatment at a temperature above 60° Centigrade, the bacteria therein become so weakened that they are readily destroyed by ultra violet rays. It is claimed that by this combination treatment the milk is not given a heat treatment sufficient to materially alter the flavor and that a very short exposure to the ultra violet light is sufficient to completely sterilize the liquid.

Walker (British patent 16,110, July 12, 1911) sterilizes milk, beer, water or other liquids by allowing the liquid to flow from perforated distributing pipes over inclined quartz plates and thence downwards over the surface of two or more corrugated metal plates. These plates are arranged around a mercury vapor lamp and the liquid is collected in a trough placed below the lower edges of the plates.

Sterilization of Fats.

Fats, butter and the like are sterilized by means of ultra violet rays according to Soc. Le Ferment (French Pat. 400,921, Mar. 17, 1909) in the following manner: The fat is spread in a thin layer on the surface of an endless band or on a drum. The movement of the band carries the layer of fat past a number of lamps which emit ultra violet rays. These lamps are provided with a reflector. The fat is removed from the band by means of a scraper after it has passed the lamps. The band may be heated or cooled as desired.

Sterilizing Barrels.

From his experiments, *Moufang*, (Kirm. a. d. Nahe Allgem. Z. Bierbrau. Malzfab. 43, 151-5, 1915) concludes that by the application of ultra violet rays for sterilizing barrels (by means of a specially constructed quartz lamp which could be inserted through the bung hole) the biological condition of pitched barrels may be greatly improved, but that perfect sterilization in a biological sense is not obtained by the present appliances.

Relative Germicidal Properties of the Rays.

In a discussion of ultra violet rays and their practical applications, *Berthelot* (Soc. Ing. Civil de France, Proces-Verbal, 1911, No. 15, 147) divides ultra violet rays into four classes as follows: (1) Solar ultra violet rays (wave length = $0.4\text{-}0.3\,\mu$), comprising those ultra violet rays which reach the surface of the earth from the sun. These rays have not a destructive action on organisms, but act chemically and physiologically in a manner not greatly differing from that of the violet and blue rays of the visible spectrum. (2) Medium ultra violet rays (wave length = $0.3\text{-}0.2\,\mu$). These rays exert a germicidal action, while chemically they play a similar part of many enzymes and catalyzers in effecting decomposition. They produce numerous chemical reactions, mostly of an exothermic irreversible character. Such rays are used on a large scale for bleaching olive oil. (3) Extreme known ultra violet rays (wave length = $0.2\text{-}0.15\,\mu$) which possess similar germicidal properties to the rays of the preceding class, but chemically they act synthetically, producing reversible reactions of an endothermic character. With the aid of these rays it has been found possible to effect synthesis of carbohydrates, and of formamide, which may be regarded as the prototype of proteins. (4) Unknown ultra violet rays (wave length = $0.15\text{-}0.1\,\mu$). Only the existence of these rays is known, but nothing as to their properties, for they are absorbed by all substances, even by the thinnest film of gas. The rays belonging to classes (2) and (3) are produced for technical purposes by arc lamps and by quartz mercury vapor lamps. These rays are used in medicine for the treatment of skin diseases and for destroying pathogenic organisms. They are also being used extensively for the sterilization of water and for similar purposes.

Manner of Destruction of Living Cells.

The mode of action of ultra violet radiation in producing sterilization is discussed by *Burge* (Journal of the Franklin Institute, 264, 1916). Since the life of a living cell is dependent upon its intracellular enzymes, and since the ultra violet radiation destroys enzymes, a theory has been advanced that ultra violet radiation kills living cells by destroying the enzymes of the cell. In an investigation of this theory pure cultures of B. prodigiosus, B. fluorsceens, B. liquefaciens, were chosen because they possess the property of liquefying gelatine, this property in turn being dependent upon the intracellular proteolytic enzymes. Twenty-five cubic centimeters of liquid containing great numbers of B. prodigiosus were exposed in an open vessel to the radiation from a quartz-mercury vapor burner operating at 140 volts, 3.3 amperes, at a distance of 10 centimeters until the bacteria were dead. The dead bacteria were thrown down by means of a centrifugal and washed in physiological saline. The mass of dead bacteria was ground up in a mortar with sand and 30 per cent. alcohol, thus extracting the intracellular enzymes from the dead bacteria. All of the bacteria named above were treated after this manner. Ten cubic centimeters of the alcoholic extract of the different kinds of dead bacteria were introduced into separate test-tubes containing gelatine. Ten cubic centimeters of liquid containing the different kinds of living bacteria were also introduced into tubes containing gelatine. These tubes were permitted to stand at room temperature for 96 hours. At the end of this time the extent to which the gelatine had been liquefied in the different tubes was measured. The extract of dead B. prodigiosus had liquefield 7 mm. of gelatine; B. fluorescens, 6 mm.; B. liquefaciens, 10 mm.; B. pyocyaneus, 4 mm.; N. proteus vulgaris, 5 mm., and B. subtilis, 4 mm. If the amount of gelatine liquefied by the living bacteria be compared with that liquefied by the extract of the corresponding dead bacteria, it will be found that there is very little difference in the extent of liquefaction. It is therefore assumed that while the ultra violet rays had killed the bacteria, it had only slight effect on their intracellular enzymes.

Henri (Compt. rend. soc. biol., 73, 323) has found that the destructive action of ultra violet rays toward the life of organisms is almost exactly proportional to the coefficient of extinction of protoplasm; this proportionality indicates that the action of ultra violet rays on micro-organisms follows the law of photochemical absorption which has been found for the majority of photochemical reactions, and also that the mechanism of the action of ultra violet rays consists in a direct reaction on the cellular content and not in an indirect action, such as the formation of hydrogen peroxide, etc. The rays of greatest destructive power penetrate only a few thousandths of a millimeter into the interior of organisms and it is only for extremely small organisms that the action of these rays is analogous to a simple photochemical reaction. The velocity of the reaction produced in hydrogen peroxide or an acid solution of potassium iodide is greater (for a given intensity of irradiation) for discontinuous than for continuous irradiation; this difference is due to processes of diffusion which take place during the periods free from irradiation. In the case of bacteria there is no difference between continuous and discontinuous irradiation. With larger organisms the effect of continuous is greater than of discontinuous irradiation in spite of the diffusion processes concerned, this difference being probably due to processes of reparation in the organism which play the part of reversible reactions, the general effect being comparable to a complex photochemical reaction.

Burge and *Neill* (Am. J. Physiol. 38, 399-403, 1915) have found that fluorescent bacteria (non-spore formers) are much more resistant to ultra violet light than non-fluorescent organisms. It is assumed that fluorescent bacteria are able to convert the short wave lengths into longer wave lengths and thus escape their protein-coagulating power.

Bazzoni (Am. J. Pub. Health 4, 975-92, 1914) states that the full radiation from certain sources of light containing waves below 250 in length, will kill bacteria. Isolated ultra violet rays (250-280) will not affect bacteria in one drop of water in an hour exposure. Isolated ultra violet rays as short as 220-225 will kill only after several hours, even when the isolated radiation is of the same intensity as that contained in the rapidly destructive full radiation. The destructive power increased with the decrease in wave length. The destructive action of ultra violet light is therefore considered by Bazzoni to be probably dependent on its association with longer radiations.

The mycoplasma of bacteria, according to *Stoklasa* (Lentr. Biochem. Biophys. 18, 370) are very sensitive toward ultra violet rays. Azotobacterium was killed by the rays within 8-10 seconds at a distance of 10 centimeters.

Vallet (Comptes. Rend., 1910, 150, 632) has studied the action of ultra violet rays, generated in a quartz mercury lamp, on various solutions containing Bacillus coli communis. It is found that liquids such as ethyl alcohol, glycerol and certain saline solutions, are easily traversed by the rays, but albumin, peptone and oil for example, are strongly opaque. Moreover, compounds like the latter seem to be additive in their effect, for solutions containing amounts of them which separately would not be sufficient to stop the rays, no longer allow them to pass when present together.

(To be continued in the August issue.)

PLATINUM CONSUMPTION OF THE UNITED STATES

In the article on Platinum Deposits of the World, prepared by the Geological Survey and published in Commerce Reports for April 23, the statement was made that the United States alone apparently uses about 65,000 ounces of fine platinum a year. The Geological Survey has corrected this statement as follows: Domestic refiners produce 65,000 ounces of fine platinum annually from the United States. The total quantity of refined platinum used each year in the United States is about 165,000 ounces, imports contributing 100,000 ounces.

Iodine, Iodoform, Anaesthetics, Etc.

Lambert-Georgin Chemicals Corporation, Manhattan, has been incorporated under the laws of New York, with a capital of $100,000, to manufacture products of soda, and iodine, iodoform and various anaesthetics. The incorporators are F. Kriegel, M. Hotchner and L. F. Corca, 56 Pine Street, New York City.

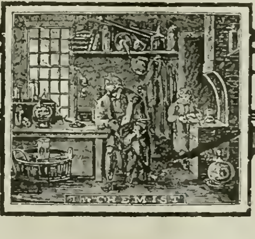
CHEMICAL INVESTIGATION
EFFICIENCY & CONTROL

CONDUCTED BY CHARLES B. DAVIS, F.C.S.



ALL classes of work covered by the following subjects will be done for readers of "The Chemical Engineer" through this department by Mr. Davis: Special research of every description; analysis and reproduction of any commercial product; prevention of waste and utilization of by-products on the most economical basis; valuation of raw materials; food analysis, and disputed points in regard to adulteration, labeling, and the enforcement of pure food laws; bacteriological and enzymatic examinations, including fermentation tests, pure yeast cultures, beverages of all kinds; development of chemical inventions and industrial processes; examinations and advice on special machinery.

Inquiries of a minor character will be answered on this page, while major matters involving personal investigations, analyses, etc., will, if desired, be treated confidentially through the mails. All questions, materials for analysis, or letters leading to the opening of negotiations for special work will receive prompt attention if addressed to

CHARLES B. DAVIS,
Care of "The Chemical Engineer," 118 East 28th Street,
New York City.

J. P. G. You are correct; there are many cases where the melting points of euteactic mixtures change. I have received the samples from your "works control" laboratory, for the checking of the various determinations and will report the results to you, at the earliest possible moment.

R. J. T.—Of the total humic substance (4 to 5%) present in maple leaves, about 2% becomes water soluble and suitable for fertilizer after four days of decomposition. During decomposition this solubility in water at first increases and then decreases until after 156 days it disappears completely.

R. T. S.—For spray irrigation the capacity of a pump usually is stated in gallons of water per minute of time. The following data of equivalents will, I am sure, assist you in converting local irrigation units into gallons and acre-inches for the estimating purposes:

1 acre-inch equals 27.152 U. S. gallons.

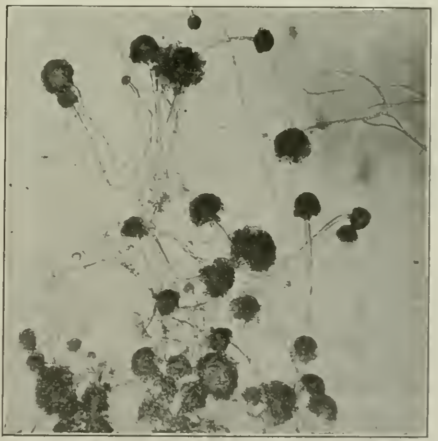
1 acre-inch equals 3.630 cubic feet.

1 acre-inch per hour equals 452.50 gallons per minute.

1 acre-inch per hour equals 1.009 cubic feet per second.

S. P.—The only superiority Saccharin Benzoylsulphonic Imide, $C_7H_5NO_3S$, or $C_6H_4(CO)SO_2NH$, has over cane sugar is its enormous sweetening power in a very small bulk, being 550 times the sweetness of sugar, and still detected in dilutions of 1 in 70,000 parts of water. It possesses absolutely no food value, is non-fermentable, and in anything but extremely small doses is injurious to the health. It is a coal tar manufactured product, and aside from its intensified sweetness and antiseptic qualities it has little or no value.

M. B.—I am in receipt of your peach pulp, and find it badly contaminated with eurotium aspergillus glaucus, which is a mould growth containing a sugar splitting enzym and a species of aspergillus oryzae. Its microscopical appearance (see microphotograph) is branched mycelium with chains from the ends of which are club-shaped, swollen mycelium threads. I would recommend that your canning plant be subjected to a thorough investigation, and that you supply me with data as to the temperatures you are using, the duration of same, together with samples of the raw and preserved fruits, so that I may ascertain the cause of the contamination.



Charles B. Davis.

Those whose inquiries to this department have not as yet received attention must bear in mind that unless replies by mail are specifically requested, communications can only be considered in the order of their receipt.—Editor.

DISTILLATES

News Notes of Chemical and Allied Industries

Addition to Bayway Plant.

The Bayway Chemical Company, Elizabeth, N. J., will erect a subsidiary building at its Bayway plant.

Interstate Chemical Co. Addition.

Plans have been filed by the Interstate Chemical Co., 673 Garfield Avenue, Jersey City, N. J., for an addition to its plant.

Carbo-Hydrogen Co. to Erect Factory.

The Carbo-Hydrogen Company of America, Columbus, Ohio, will erect a factory building on ground recently purchased from the Rood Box Company.

To Increase Bleached Pulp Output.

The paper mill at Petowsky, Mich., will construct an addition to its bleach manufacturing plant which will enable it to take care of the increase in pulp production.

Addition to Jackson Chemical Works.

The recently incorporated Jackson Chemical Works, Irvington, N. J., has filed plans for the erection of a one-story addition to its plant at 487 Chancellor Avenue.

Larger Plant for Seydall Company.

A three-story addition will be made to the chemical plant of the Seydall Manufacturing Company, 88 Forest Street, Jersey City, N. J. The cost will be about $34,000.

New Chemical Plant for Klipstein.

Contracts have been awarded by E. C. Klipstein & Co., Chrome, N. J., for the erection of eight buildings for their proposed new chemical plant at South Charlestown, W. Va.

American Manganese Co. Acquires Steel Plant.

The plant of the Lochiel Steel Company, Harrisburg, Pa., has been acquired by the American Manganese Manufacturing Company, Bullitt Building, Philadelphia, and will be subjected to improvements which will give it an initial capacity of 125 tons of pig iron and 12 tons of ferro-manganese per day.

Filter Press Companies in Merger.

The Kelly Filter Press Company, The Sweetland Filter Press Company and the American Filter Company have consolidated; the new organization is to be known as the United Filters, Inc., with home offices at 321 Felt Building, Salt Lake City, Utah, and eastern offices at 36 Flatbush Avenue Extension, Brooklyn, N. Y.

Mullen Leather Co.

Mullen Leather Co., Boston, Mass., has been incorporated with a capital of $20,000. The incorporators are S. J. Mullen, S. Starsier, Charles H. Poor.

Oils, Colors and Chemicals.

B. Brown & Bro., Inc., New York City, has been incorporated with a capital of $100,000 to manufacture oils, colors, chemicals. The incorporators are J. C. Brown, D. R. Bernstein and L. Sktuch.

New Rahway Chemical Company.

The Rahway Chemical Manufacturing Company, Rahway, has been incorporated under the laws of that state with a capital of $25,000 to manufacture chemicals. I. S. Joseph, G. H. Adler, J. B. Eiseman, Rahway, are the incorporators.

Drugs; Chemicals; Toilet Goods.

Loraine Chemical Works, Inc., Wilmington, Del., has been incorporated with a capital of $75,000 to deal in drugs, chemicals and toilet goods. The incorporators are W. G. Graidstaff, C. E. Tate, R. N. Thomas, C. C. Pitts, E. F. Curtis.

$1,000,000 Chemical Company.

The Advance Coal Company has been chartered in Delaware with a capital of $1,000,000 to manufacture chemicals. The local Wilmington, Del., incorporators are M. L. Rogers, L. A. Irwin and Harry W. Davis.

Drugs and Chemicals.

C. H. Hall, Plainfield, N. J., has been incorporated under the laws of that state with a capital of $25,000 to manufacture and deal in drugs and chemicals. The incorporators are Charles H. Hall, Elizabeth T. Hall and Louis P. Wilson, Plainfield.

Colors and Dyes.

With a capital of $5,000, the Radcliffe Color and Chemical Works, Elizabeth, N. J., has been incorporated under the laws of that state to manufacture and deal in colors and dyes by David D. Radcliffe and John J. Smith, Elizabeth, and John H. Strawbridge, Hillside Township, Union County, N. J.

Petroleum Refinery.

The Transportation Petroleum Company has been incorporated under the laws of Delaware to refine petroleum and distribute its products. The capital is $1,000,000, and the incorporators are F. Fried, G. M. Healy, New York, and Lucian Ross, San Antonio, Texas.

FOREIGN TRADE OPPORTUNITIES

These Opportunities for Foreign Business Relations Are Made Public by the Bureau of Foreign and Domestic Commerce, of the Department of Commerce, Washington, D. C. Names, Addresses and Details May Be Obtained from the Bureau or Any of Its Branches. Refer to the Number of Each Opportunity and Place Inquiries for More Than One on Separate Sheets.

Drugs; Dyes; Dyestuffs; Chemicals.

24830—Agencies are desired by a man in England for the sale of drugs, crude and refined, dyestuffs, dyes, chemicals, and all types of allied products. References.

Aluminum Sulphate.

24828—A company in England desires to purchase 10 to 12 tons lots of sulphate of alumina, 17 per cent. to 18 per cent. ground, and free from iron. Quotations should be made c. i. f. Manchester, if possible. Payment will be made by cash against documents in England. References.

Colors and Chemicals.

24809—A company in England wishes to buy chemicals and colors for textile trade, cotton, silk, wool, leather, and paper makers. Samples and complete analysis should be submitted. Payment will be made by cash against documents through New York bankers. Quotations should be made c. i. f. or f. o. b. any port. English weights are preferred. References.

Aniline Dyes.

24829—A firm in French Indo-China wishes to be placed in communication with American manufacturers and exporters of sewing machines, scales, files, nails, sewing needles, sheet zinc, baled newspapers, oil cloth, aniline dyes, corned beef, and canned fruits. Quotations should be made c. i. f. destination, if possible, otherwise f. o. b. American port. Payment will be made by sight draft against documents. Correspondence may be in English. Reference.

Coke.

24808—A foreign trade adviser of a foreign government is in the market for coke suitable for mining and metallurgical establishments. The coke should not contain more than 10 per cent. of ash and moisture content should not exceed 2 per cent. The immediate needs are for 10,000 tons delivered at Cartagena or other Spanish port, 9,000 tons delivered at Tunis, and 6,000 tons at Marseille or St. Nazaire. A change in ports will be allowed. If arrangements can be made at once, contracts can be made for further deliveries in 1918.

Tungsten and Molybdenum Filaments.

24106—A man in Spain desires to purchase filaments of tungsten and molybdenum for the manufacture of electric lamps. He also wishes to entertain an agency proposition. Quotations should be made c. i. f. Vigo or destination. Cash will be paid in New York. Correspondence may be in English. References.

Chemical Products.

24535.—A man in France is in the market for agricultural machinery, watering apparatus, hardware, tools, locks, tin and zinc articles, electrical supplies, heating and lighting apparatus, household furniture, bicycles, rubber wheels, rubber goods, chemical products, and supplies for painting and photography. Catalogues should be submitted.

Soap-Making Materials: Cautic Soda.

24014—An importer in Mexico is desirous of being placed in communication with American manufacturers and exporters of bicycles, motor cycles, automobiles, hardware, corrugated metal plates, tools for mechanics and artisans, paper manufacturers' supplies, and soap-making materials, especially caustic soda.

Chemicals, Chemical Supplies and Machinery.

24513.—A man in France desires to purchase or represent American manufacturers and exporters of all kinds of chemicals, chemical supplies, and machinery for chemical plants. Quotations should be made c. i. f. French port, or f. o. b. American port. Payment will be made by cash against documents if desired. Correspondence may be in English. Reference.

Pharmaceutical and Industrial Chemicals.

24543.—An agency, on a commission basis, is desired by a man in Peru for the sale of small electrical devices, canned goods and foodstuffs in general, paper and paper products of all kinds, chemical products for pharmacies and industries, and small hardware and supplies for trunk, saddle, etc., manufacturers. Quotations should be made c. i. f. destination. Payment will be made by cash against documents at destination. Correspondence may be in English, but Spanish is preferred. References.

The Organization of National Industrial Research

There is no question but that the chief occasion for Germany's marvelous powers of offense and defense in the present world struggle, and for her dominating position in the manufacture of chemical products before the war, and in their distribution throughout the world's markets, was due primarily to the perfection of the Empire's facilities for industrial research. The importance of this factor in national life was not appreciated in an equal measure by other rival lands. It is, however, now felt in most European, and in many non-European countries, that no time is to be lost in arranging for a much more exhaustive and comprehensive scheme of industrial research than has hitherto been the rule.

In our own country there is an admirable start in this direction, but much more needs to be done.

The results obtained during the past few years, in certain restricted fields by the Bureau of Standards, the Bureau of Mines and various bureaus of the Department of Agriculture, reveal, in a striking manner what can be done on a vaster, more comprehensive scale. There is an enormous opportunity for combining public and private initiative. In the rapid organization and mobilization of the country's resources for the vigorous and successful prosecution of war, we are witnessing the creation of a mechanism, which should function normally during peaceful times in assuring the highest efficiency and the steady, swift advance forward of our manifold industries. Some of them—not many—reveal admirably organized individual efforts to insure adequate progress in the field of research. Reference may be made here to the fine equipment of some chemical companies, such as the du Pont Company, and constituent parts of the recently organized National Aniline and Chemical Co., Inc., the Eastman Kodak Co., and a few others.

What we need, however, is a much higher degree of combination and co-ordination, such as is aimed at across the waters.

The British "Advisory Council for Scientific and Industrial Research" is dealing with this problem in a systematic, intelligent manner, collating all available material from other countries and focussing the attention of the British Government and the British people upon the imperative necessity of prompt and generous action.

The Council has just issued its first publication, based upon elaborate studies of what is being done in this country to advance industrial research, made by A. P. M. Fleming, M. I. E. E.

His paper entitled "Science and Industry: Industrial Research in the United States of America," is finely illustrated and is a well-balanced portrayal of what American experience and practice can offer in a suggestive, educational way to British industries.

In a closing chapter Mr. Fleming summarizes his conclusions and recommendations. These apply frequently with such pertinence to the general status of chemical industry in our own country, and more specifically to the interests of the coal-tar chemical industry as it is struggling to gain a permanent foothold, that we quote them at some length:

"While there are prominent British manufacturers who appreciate the potentialities of industrial research, it must be conceded that as a body they consider such investigation to be an expensive luxury. On the other hand, during the past two years there has been disclosed in British industries an enormous latent capacity for adaptability to entirely new lines of manufacture, many of which have depended for their development upon scientific research. The research facilities, however, that have been created to such an extent during the past two years are as yet quite disproportionate to the magnitude of British industry, and it is highly desirable that the present awakening to the use of science should be fostered, and research facilities suitably organized.

"For this purpose it is essential that any national scheme of research be designed on ideal lines to which existing organization should be subordinated, so that in this way the development can proceed progressively until ultimately the plan is consummated.

"From the standpoint of the individual firm, the most effective weapon in industrial competition is the application of new knowledge resulting from research applied to some immediate industrial problem. In pursuing an investigation, however, toward a definite goal, it is well known that many promising ramifications are often disclosed, which, when followed, lead to results that may be more valuable even than the original objective. In this way it may often happen that a research carried out in the interests of one industry may lead to results which prove invaluable if applied to some quite different industry. The higher forms of research, more especially those in the field of pure science, should therefore be carried out on national lines, so that any results that are derived can find application in one or other of the numerous national industries.

"It is even more important that such research be organized on lines which will link up the scientific resources of the Empire. The work of the Institute of Science and Industry in Australia, and the research now being developed by the Canadian Pacific Railway, together with similar efforts that may be made in other parts of the Overseas Dominions, should be linked up with a national scheme in this country. Apart from the interchange of scientific knowledge, such an Imperial scheme would assist the utilization of raw materials, and in this way foster the development of the natural resources of the Empire. It is quite as important for manufacturers in Great Britain to interest themselves in any means which will improve and cheapen their raw material supplies as it is to direct scientific methods to the cheapening of manufacturing processes. An Imperial research organization might not only result in the development of means for cheapening the production of raw materials, but also, where new materials are discovered in the Overseas Dominions, assist in finding suitable outlets for their use.

"An important consideration affecting industrial conditions after the war is that considerable manufacturing resources, comprising plant, machines, tools, and trained labor will have accumulated, some of which may be turned to national benefit if they can be adapted to the manufacture of products hitherto obtained from abroad. In thus developing new lines of manufacture, organized research may be of very considerable benefit. In order thus to meet international competition it is necessary to bring each manufacturing process to the highest degree of efficiency by the elimination of haphazard and wasteful methods.

"With regard to the financial aspect of research, experience in the United States shows that the efficiency of a well-organized laboratory increases considerably with its size, and, moreover, only the large laboratories can employ methods of full-scale manufacture, which not only materially assist in the efficient development of new products, but also secure considerable revenue from the sale of commodities produced in this way. Thus the annual maintenance cost of the laboratory of the Eastman Kodak Company is $150,000, representing less than 1 per cent. of the annual profits of the company.

"Viewing American experience in the light of the considerations described, the following seem to be the the most important of the alternative schemes of research that might be employed in Great Britain:—

(*a*) Research laboratories in individual works.
(*b*) Research laboratories for a group of works in the same industry.
(*c*) The centralization of research in the universities or colleges.
(*d*) An Imperial centralized laboratory for the whole of industry.

Individual Works Laboratories.

"The most effective way of conducting industrial research would be to equip each works with its own laboratory. By this means the most intimate needs of the firm could be studied and effectively dealt with, and such a close combination of works, organization, and scientific investigation would probably result in a number of very efficiently conducted firms. It is clear, however, that only the largest works could support laboratories on an extensive scale. An enormous amount of overlapping would occur, since each laboratory in the same industry would probably carry on very similar work; most firms could not stand the financial burden of such a laboratory; there would be an insufficient number of really first-class research men available to staff such laboratories; and, it would hardly be practicable to carry out investigations of a purely scientific character, since the possibilities of turning a large part of the results of investigations to account in any one firm or industry would be comparatively small. Further, while by such means individual firms would be able to compete keenly with each other, their scientific resources would not be organized in the best way to meet competition in international markets.

"Complete research laboratories in individual works only appear possible in the case of very large organizations, although, as noted later, individual laboratories adapted for dealing with immediate needs are highly desirable when operated in conjunction with a larger research scheme.

Research Laboratories for a Group of Works in the Same Industry.

"Different firms in the same industry employ very similar manufacturing facilities, and in order that the greatest possible improvement can be made in tools, methods, and processes, it is desirable that the various firms should pool for their common benefit all the experience and research facilities they possess that will assist this object. For this purpose a central laboratory might be arranged for each industry or for a group of similar firms in the same locality.

"In those cases where firms have secret processes in connection with which investigations are required, these would be carried out by each firm on its own account. Many such processes, however, are of much less importance than is commonly supposed, and the experimental work thus involved would probably represent not more than a small portion of the total research requirements.

"Such arrangements are already in vogue to a limited extent in this country; for instance, a central laboratory for research work is maintained in the Sheffield district, where two of the largest steel firms in intimate commercial alliance support a common research laboratory. In other cases facilities for common research have followed on the fusion of the commercial interests of two separate firms, as has occurred in the pottery district. While it may be argued that the pooling of resources may entail some self-sacrifice on the part of larger firms, from which their smaller competitors would benefit, this is probably not a very important matter, since many processes could for financial reasons only be taken advantage of by the largest firm. In any case, however, while such combinations might in the case of some firms involve a temporary loss, improvements arising from joint research would probably enable every firm to recoup far more than it expends, owing to the increased amount of business and greater working economy arising from the application of the discoveries made. The time was never so opportune for such co-operations, and never have competitive firms been so ready to share mutual interests.

The Centralization of Research in the Universities and Colleges.

"The most extensive facilities for research in this country are at present possessed by the technical colleges and universities, and these are to some extent employed for dealing with miscellaneous investigations required by local industries. These facilities might be arranged so that each university served as a research station for one or other of the principal industries.

"There are, however, many objections to this course. The function of the modern university is to educate, and its equipment and staff should be directed primarily to this end; the staff is not, as a rule, intimately in touch with industry, and the amount of research necessary for the industries of this country is far beyond all the resources of the universities. On the other hand, research is one of the finest possible means of educating young men for industrial employment, and consequently every encouragement should be given to graduates to pursue some research work under the guidance of an experienced experimentalist. For educational purposes the character of the research should be such as to develop the student's capacity to think for himself and increase his powers of observation and logical deduction.

"At the present time, with the exception of the work of the National Physical Laboratory, most research in pure science is carried on in university laboratories, and such work is eminently suited to the capacity of the university staff. From the experience of the States it is clear that to be most effective in an industrial sense research investigations should be undertaken by a staff specially devoted to the purpose, and as far as possible also with equipment not required to be used for teaching purposes. In such cases there appears to be very little to be gained by attaching such special research laboratories or experiment stations to the universities. They might equally well be placed at other and possibly more convenient centres of industry.

A Centralized Imperial Research Laboratory for the Whole of Industry.

"The single laboratories dealing with the research requirements of each industry might all be grouped together in one centre, and controlled by a board largely represented by manufacturers.

"Such a combination would possess many advantages over separate laboratories. For instance, the cost of maintenance would be less, and through the common use of library, power supply, machine and other workshops, the first cost would also be lower. By far the greatest advantage, however, would be the benefits derived from the corporate life of such an institution, and the free interchange of experience and discussion of research work between the staffs of the various industrial sections. As already pointed out, in the pursuit of an investigation much new knowledge may be disclosed which has an important bearing on industries quite different from that of the original objective. In a laboratory confined to the needs of a single industry such new knowledge might be entirely lost, or if put on record might not come to the notice of those to whom it would be of the utmost benefit. In the centralized institution such a risk would be reduced. Further, such a laboratory would be best adapted for co-operating with the research institutions in the Overseas Dominions, and in fact would serve as a scientific focus for the whole Empire.

"The staff of the laboratory would comprise a senior grade, representing the directors or heads of each industrial division; an intermediate grade, representing the principal body of research men; and the juniors, who would principally consist of graduates recently drawn from the universities. The senior staff would be permanent. The intermediate men would be continually migrating into industry as their value to manufacturers became appreciated, and this tendency would be encouraged so as gradually to permeate industry with well-trained scientific men. The junior staff would be permitted to employ part of their time in the laboratory in preparation for higher degrees, and in this way their appointment would be equivalent to a fellowship such as that tenable in some universities for graduate research, with the advantage that the training period would be spent under first-class research men, and the work undertaken would in most cases be of live industrial interest. The juniors would in course of time be promoted to the intermediate work.

"In order to utilize every scientific asset the staff and facilities of the universities and of private research workers would be registered and incorporated as auxiliary to the central laboratory. The university staffs could from time to time for convenient periods take up research work in the central organization itself, and in this manner keep closely in touch with modern progress.

"While the function of the laboratory would be primarily to deal with problems confronting manufacturers, a considerable amount of original research in pure science would need to be done. On the other hand, the laboratory should be provided with means to carry on the actual manufacture of new products until this is undertaken by a regular commercial concern. While the first cost and the maintenance for some years would have to be provided out of public funds or by levy on the profits of industry, the institution ought to become self-supporting in time from the sale of products manufactured and from the licenses granted to manufacturers in connection with new or improved materials, processes, or tools.

"Under present manufacturing conditions it frequently happens that the user of materials has to carry out the research necessary for their improvement. Fundamentally this practice is wrong, and such work should be carried out by the supplier. With the help of a centralized institution it would be possible for each branch of every industry to have its own research carried out there under the guidance of its governing body or trade association.

"The importance of the collation of all scientific information, not only that pertaining to contemplated research, but also that of use in industry generally, has already been alluded to. The centralized organization affords the best possible means of doing this, and also of disseminating it to those to whom it will be the greatest value. The laboratory would also issue bulletins of the work it carries out, and might also undertake the preparation of text-books in the most important and advanced branches of technology. The heads of the different sections of the laboratory would require to keep in close touch with the firms of the industry they represent, in order to carry out where necessary full-scale manufacturing experiments in works, and with the National Physical Laboratory, which would deal with all matters pertaining to standards and research connected therewith.

"The establishment of such an organization would tend to cause firms to install their own laboratories in co-operation with the central laboratory for dealing scientifically with manufacturing troubles and special research problems incidental to their own products.

Conclusions.

"The most important conclusions that emerge from the above facts and considerations may be shortly stated.

"Industry is the basis of national prosperity, and every resource should be used to facilitate its progress. The success, however, of any comprehensive scheme of research depends largely upon the attitude of the manufacturers, and it is therefore of high national importance that they should not only appreciate the value of the application of science in industry, but also co-operate in assuring that it is applied systematically and sufficiently. Among the questions that arise immediately out of the need for industrial research is that of the education and training of men for all grades of industrial employment. The full benefits of scientific investigation will not be obtained unless the results are applied by suitably trained men. There is urgent need for consideration on national lines of means for the better education and training of youths who will be the future skilled workmen; and the demand expressed by many for a more important place for science in education needs no emphasis. It is not less necessary to give attention to the scientific training of those who proceed to the higher positions in industry from the universities, and particularly to impart to such students a thorough knowledge of the fundamentals of manufacturing economics. The development of research on a large scale, and the consequent possibilities of absorbing and lucrative employment, will tend to attract to the ranks of industry many of the ablest young men who nowadays enter non-productive professions. In this way their value from a national point of view will be immeasurably increased.

"A new phase in industrial and economic life is commencing, and its development will be governed very largely by the extent to which new scientific knowledge is obtained and turned to the benefit of mankind. It is by the progressive use of research, every advance of which opens up ever wider industrial possibilties, by the fullest employment of the nation's inherent manufacturing capacity, and by the wise co-operation of labor and capital, that the prosperity of this country can be assured."

A New Factor in the American Dyestuff Industry

For over a year there has been more or less discussion by all interested in the evolution of the American coal-tar chemical industry, as to the possibility of the entry into this field of the E. I. du Pont de Nemours Company of Wilmington.

The company has expanded enormously during the past three years its plant for the manufacture of the high explosives, picric acid and trinitro-toluene. It has created a fine plant for the production of aniline and several of its derivatives such as diphenylamine and tetra nitro-methyl-aniline, used as stabilizers, etc., for high explosives.

It was evident that the vast equipment would find but a limited field of usefulness at the end of the war and of the abnormal demand for munitions, unless it was utilized directly for the manufacture of more peaceful coal-tar compounds.

This fact has been fully recognized by the directors of the company and the decision has been made to embark extensively upon the production of artificial dyestuffs. The company's plans are formulated in the following announcement:

"We desire to announce our decision to enter the coal-tar dye industry.

"The reasons for this step might be briefly summarized as follows:

"Our development during recent years in the explosive and in several other branches of the chemical industry brings us now to the logical result of undertaking in a broad and comprehensive way the manufacture of synthetic dyestuffs and kindred products.

"The explosive and coal-tar dye industries are closely allied; both require intermediates which we manufacture in a large way; both are highly scientific and thoroughly developed and both require large technical and commercial organizations.

"We start with (1) the necessary raw materials, products of this country, and are therefore not dependent upon Europe; (2) a chemical and enginering organization second to none in magnitude and scientific attainment; (3) unequalled plant and laboratory facilities, and (4) an adequate commercial organization.

"We know the needs of the various consuming industries, that is, cotton, calico printing, wool, silk, leather, paper, paints, printing inks, etc., and plan to meet them in due time.

"Our development will necessarily be progressive, starting with certain products and increasing as rapidly as possible.

"Our technical laboratories, with a competent staff of experts, will be at the disposal of all consumers in all branches. We shall establish, and hold to, the highest standards of quality. Our prices from the start will be based upon our cost of raw materials and labor, with the end in view of establishing at this time, under abnormal conditions, cordial and enduring relations with the consuming industries.

"Back of all this is the compelling force of the country's need; if as the result of the combined efforts of all, the United States can in time, become self-contained, we are quite certain that we voice the sentiment of the consuming industries in predicting that the effort will not have been made in vain."

This announcement has the right ring!

Taken in connection with the recent merger of leading coal-tar chemical interests into the powerful "National Aniline and Chemical Co," it means that our country will possess two powerful dyestuff organizations, either one of which is potentially able to rank at an early date with the strongest of the German or Swiss color corporations. As a matter of fact the du Pont Company employs more chemists than the famous "Badische" Company.

It is an eminently wise decision to enter immediately upon the field, and gain all possible experience, technical and commercial, before the time approaches to discontinue the manufacture of explosives on the existing scale, and to face the problems of foreign rivalry, certain to accompany the resumption of normal international exchanges.

With exceptionally ample capital, and a finely organized staff of experts already familiar with the problems of coal-tar chemistry, this action of the du Pont Company contributes mightily to assure the future of our American industry. The fact alone that a corporation with a capital of $240,000,000, feels that it can safely enter upon this new field and hold its own against the prospective competition of European rivals possessing the broad experience of several decades, will do much to strengthen the determination of lesser factors, ambitious to share in building up our color industry, but hesitating over possible risks.

Government Activity in the Field of Color

There has been some misapprehension in industrial circles with regard to the nature of the work now carried on in bureaus of the Departments of Commerce and of Agriculture on the subject of colors.

The Bureau of Chemistry in the Department of Agriculture has established at Roslyn, Va., a branch laboratory, in which, under the intelligent direction of Dr. H. D. Gibbs, a number of important lines of research connected with the production of important coal-tar intermediates and the manufacture from the same of dyestuffs are being actively pushed. This class of investigation has been highly developed in the great color works of Germany and is supplemented by a vast amount of closely related research in the laboratories of the state-supported universities and technical schools. This close co-operation between governmental institutions and industrial effort is one great source of the power of the German coal-tar color branch. It contributes not only to the ability to maintain an economical supremacy, but also to the advance forward in tinctorial invention. The possibilities of discovering new classes of synthetic dyes, capable of displacing many standard favorites in point of brilliance, fastness, ease of application or cheapness, are just as marked today as at any time since Perkin made his epochal discovery. The nation whose chemists neglect to emphasize the importance of extensive and varied research, cannot hope to successfully retain a dominant position in its own or in foreign markets.

It is in full recognition of this fundamental fact that the men of science in Government employ regard it as of paramount importance to establish upon a firm basis the requisite organization for carrying out such forms of investigation in the chemistry of coal-tar compounds, as will enable us, ere long, to contribute notably to its progress, and stand upon an equality with the large corps of capable and versatile men in German and Swiss laboratories, who steadily broaden the outlook of the dyestuff industry.

Full success can be attained only when the same restless, determined spirit becomes evident among the chemical staffs of our colleges and universities, and especially of the companies actively engaged in creating our new industry.

The Bureau of Chemistry at Washington will freely place its results at the service of private initiative and co-operate with the domestic industry wherever it can advance the growth of the domestic dyestuff industry.

Logically this should lead to a very close co-ordination of efforts upon the part of Government chemists and of those connected with our leading color firms. On a small scale, all concerned must manifest that same fine spirit of co-operation, which characterizes our nation, as a whole, in facing the tremendous problems of war.

There has been an assumption that the question of the standardization of dyestuffs, which has been a topic of serious and widespread discussion during the past few months, has been taken up actively by the Bureau of Standards, in the Department of Commerce. This is by no means the case. Dr. S. W. Stratton, the director of the Bureau of Standards, has outlined recently, in great clearness, the exact nature of the work under his supervision.

According to his statement, for several years the bureau has been experimenting toward a standardization of color, not as a substance, but as a physical phenomenon, as the color of butter, of cloth or of paper. This is entirely distinct from a standardization of dyes. The Bureau of Standards seeks to make it possible to point out what is a standard color so that it can be duplicated at any period of time, and is trying to establish methods of so determining the quality of colors. The bureau is seeking to establish standard colors of dyes, but not a standardization of dyes themselves.

The question of the standardization of dyestuffs is a very complex one. It might very properly come within the purview of the national Bureau of Standards. This would mean, however, an enormous extension and enlargement of the chemical side of the bureau's work. At present sentiment in the bureau is averse to increasing the already numerous spheres of activity, in which such admirable work is being done —work which commands respect in all countries.

Phenol from American Coal Tar

The admirable way in which American coal-tar chemists are dealing with the problems connected with the exact and economical utilization of our domestic supplies of crude materials, is well illustrated in the exhaustive study on the determination of phenol in crude carbolic acid and tar oils generally, by Mr. J. M. Weiss and Mr. C. R. Downs, to be found in the next section of this issue of the CHEMICAL ENGINEER.

The method evolved by them facilitates, in a remarkable degree, the work of establishing the commercial value of the current sources of phenol. As a result of the entirely abnormal demand for phenol, in connection with the enormous demand for picric acid, the manufacture of the synthetic product has been established upon American soil on a vast scale, and has been brought to a high degree of perfection.

To some extent the manufacture has been materially modified through the employment of chloro-benzene as a starting point. There are, apparently, certain advantages in making use of this compound and in nitrating it to dinitro-chloro-benzene, before the chlorine in the molecule is replaced by hydroxyl, and dinitrophenol is obtained. The latter can be nitrated further to picric acid, or be used directly in the production of Sulfur Black and of other colors.

It is not impossible that, after normal conditions have been restored, such indirect syntheses of phenol derivatives may prove to be more economical than methods in which phenol itself is taken as the starting point.

There is, however, a very large demand for pure phenol, in the form of crystals or liquid. This should be met most advantageously by employing phenol separated by fractionation from coal tar, and suitably refined.

There is no very wide margin between the cost, under normal conditions, of manufacturing synthetic phenol from benzene and the current rate for the product early in 1914. This fact may act as a check to excessive rises in price for natural phenol, in the future.

We may logically expect that, at the close of the war, our customary consumption of phenol will be covered by a supply obtained exclusively from American coal tar. The equipment requisite for the purpose is now present and the tariff act of September 8, 1916, affords a moderate but fairly ample protection for the domestic product in a more or less refined condition.

Prior to the war there was little inducement to create an American phenol industry. In both England and Germany the industry was highly developed and perfected. The supply of coal-tar from American coke plants was limited, and totally inadequate to furnish the amount of tar oils required for use in preserving railroad ties, telegraph poles and the like. Great quantities of creosote oil were regularly imported from Europe. Market conditions were such that it was economically more profitable to use the entire stock of domestic tar oils for preservative purposes, rather than to extract the fraction of pure phenol.

At the end of the war conditions will be totally changed. The recovery of coal tar is vastly augmented. The newly-created American dyestuff industry will call for considerable amounts of phenol, the various cresols and possibly the xylenols. In addition, anthracene will be in steady demand for the manufacture of alizarin and numerous other colors derived from this hydrocarbon. As a result, the whole mechanism for securing the higher boiling constituents of coal tar, in relatively pure forms, is being perfected to such a degree that we can be independent of European sources. This will naturally mean much to the American dyestuff industry and to all branches using coal-tar crudes and intermediates as raw material.

Accurate analytical data and methods are essential to the successful evolution of these phases of the coal-tar chemical industry, and all connected therewith will accord a hearty welcome to the valuable study of Mr. Weiss and Mr. Downs.

Annatto from Porto Rico

In these days of widespread effort to emancipate ourseles from dependence upon foreign sources of drugs and dyes, attention may be profitably directed to our insular possession of Porto Rico as a region from which we can easily secure our normal supply of the natural dyestuff, annatto.

The consumption in the United States during the fiscal year 1913-14 of this coloring material was 507,000 pounds, the invoice value of which in the countries of origin was $25,340. The average invoice value per pound was 5 cents. In the fiscal year 1915-16 the import mounted to 603,000 pounds, the invoice value being $69,800, or 11.6 cents per pound.

The chief sources of annatto have been Brazil, Guiana and the French West Indies. Zanzibar and Hawaii export limited amounts. Of late years Porto Rico has contributed to the world's market. In the fiscal year 1913-14 the export was 212,000 pounds. It increased in the year following to 337,000. The price per 100 pounds, in 1913-14, at Porto Rican ports, was $4 to $5. At present it ranges from $13 to $15, according to quality.

The coloring material is found in the fruit of the bush or small tree known as *Bixa orellana,* which grows wild in Porto Rico, but is frequently cultivated in the other countries mentioned above. There is no reason why the shrub or tree should not be made in Porto Rico the subject of systematic and intensive cultivation, of as intelligent a nature as that which characterizes the present effort in India to increase the output of natural indigo and standardize the product. It might prove a valuable factor in the agricultural assets of our island possession, the climate of which seems admirably adapted for the growth of the tree and the maturing of the fruit.

This fruit consists of capsules as large as walnuts, in which the seeds are embedded in an orange yellow, sticky pulp. The treatment of this pulp, which contains the coloring matter, is usually quite primitive. In some places the seeds are removed, at the outset, from the pulp. In other regions it is allowed to stand in water for some time, undergoing a. sort of fermentation, after which the seeds are separated by the use of sieves. In still other sections the contents of the capsules are extracted directly with boiling water. A soft mass separates out from the water, and this, after being freed as much as possible from the water, constitutes commercial annatto, a bright, yellowish red paste.

The pulp at this point contains two distinct coloring matters. One, a light yellow, is soluble to quite an extent in water. The other, of a resinous nature, is bright red, insoluble in water, but soluble in alcohol and solutions of the alkaline carbonates. The residual water, after the separation of the annatto proper, is colored bright yellow.

Annatto paste is prepared for exportation in various ways. The most common is to press it into cakes weighing 2 to 3 pounds, which are wrapped in banana leaves and then packed in casks. Annatto from the French possessions is almost always shipped in this form.

Brazilian annatto is pressed into the form of small, hard, compact cylinders, externally of a brown color, internally a brilliant red. The British market is usually supplied with these cylinders.

There is an increasing tendency to ship the soft paste itself, containing about 60 per cent. of water, and packed in tins or kegs. In Europe, especially in France, annatto is submitted frequently to a process of refining or concentration, and is put upon the market in the form of tablets, containing four times as much coloring matter as the cruder material, shipped from the tropics.

The seeds contain a relatively small amount of color, and are exported when market conditions are favorable, as at present.

The young bushes of *Bixa orellana,* after the growth of a year and a half, yield from one-half to one pound of this crude annatto, and there is a steady increase in the yield with each additional year of growth.

There is a widespread use of annatto in coloring confectionery, butter, cheese, various sauces, and other articles of food. The color is also employed for varnishes, lacquers, wall paper, fancy papers, water colors and oil colors. In calico printing there is a limited use, as well as in the dyeing of silk, to which annatto imparts a particularly bright and lively tint. The very fugitive character of the color prevents, however, any very extended use in the textile industries.

In New York markets the best grades of annatto now command $33 to $34 per 100 pounds. The seeds sell for $11 to $14.50.

The American Supply of Toluene

There is much to indicate that the demand for toluene in this country will shortly become as pronounced as was the case in 1915. The managers of coke-oven plants and tar-distilleries report that inquiries for the article are multiplying at a rapid rate. As hitherto, nearly all is required for transformation into trinitrotoluene—TNT. The notable increase in demand results from the completion of the plans of the Ordnance Bureau, which evidently involve the ordering of vast amounts of high explosive shells.

Practically all of the output of toluene for months ahead was engaged some time ago, to meet the orders of our European allies and current needs of the American military establishment.

It will be difficult to bring about any rapid increase in the output of toluene from coke plants. Practically all of our modern by-product coke-oven installations are now equipped with benzol scrubbers, which recover nearly all of the benzene, toluene and xylene present in the current of gas issuing from the retorts.

There would appear to be but two methods of relieving the shortage in this class of high explosives, unless the ordnance experts devise methods of utilizing guncotton and dynamite for the purposes in view.

The first method is to increase the relative amount of picric acid used for shells. This would mean falling back to the conditions which existed prior to the recognition of the marked advantages of TNT, as far as regards safety and convenience of handling, which much more than counterbalance its slight inferiority in explosive power, weight for weight.

In this connection it might be pertinent to inquire whether experiments have been conducted as to the desirability of mixing the two materials. It is possible that to some extent, if not entirely, the disadvantages and danger associated with the use of picric acid might be modified or lessened when the two explosives are mingled or found together.

The second method is to adopt widespread measures for recovering the benzene and toluene, present in our illuminating gas. This would involve the erection of benzol scrubbers, quite similar to those employed in coke plants.

As the luminous properties of gas depend largely upon the presence of the vapors of these aromatic hydrocarbons, it would naturally be necessary to carburet the gas on leaving the scrubbers, in order to introduce an equivalent quantity of other non-saturated hydrocarbons.

All of this involves additional plant in our gas works, which, however, can be utilized in times of peace, as there will be an increasing demand for benzene and toluene to replace gasoline for use in motors.

Should the great conflict be materially prolonged and the intensity of the artillery, as a dominating factor, be notably increased, it is evident that American coal-tar chemists will play a prominent part in insuring final success.

Situation of the Leading German Artificial Color Company

The famous "Badische Anilin und Soda Fabrik" of Ludwigshafen, on the Rhine, the strongest of the German companies engaged in the manufacture of colors, has published its balance sheet for 1916.

The figures are of peculiar interest at the present time, as are also the accompanying statements of the directors, although they reveal little concerning the specific activities of the great organization. It is generally understood that the manufacture of dyestuffs has been largely replaced by that of munitions of war and hospital supplies. The company is also doing important work in the synthetic production of ammonia, which is transformed by Ostwald's method into nitric acid.

From the report it is seen that while in 1915 creditors stood for 18,750,000 marks, roughly a third of the share capital of 54,000,000 marks, the figures now stand at no less than 116,000,000 marks, or more than double the share capital. This extraordinary increase is explained by the Government advances, which are repayable at far distant periods.

Advances to the Government have resulted in increasing the investment account from 79,790,000 to 111,390,000 marks. The Augusta Victoria Mine has not come up to expectations and has, it is stated, suffered from the extraordinary labor difficulties. To safeguard supplies of lignite, two lignite mines have been acquired. On the other hand, shares of the Union of Chemical Works at Zeitz, which under the changed circumstances were not considered of special value, have been sold.

The figures of the published balance sheet, in marks, are as follows:

	1914	1915.	1916.
Brought forward	2,236,609	2,627,800	2,893,875
Profit on products. .	28,632,148	33,867,711	40,614,837
Interest	591,891	1,150,017	2,012,462
Total	31,460,648	37,645,528	45,521,174
Expenses	5,706,150	5,286,644	5,822,960
Interest on loans.	950,175	922,444	886,309
Written off	9,005,517	11,607,571	12,369,258
Profit	15,798,806	19,828,871	26,442,647
Extraordinary reserve. . .	3,000,000	3,000,000	3,000,000
Dividend	8,550,000	10,800,000	10,800,000
Dividend per cent.	19	20	20
Bonus of 8 per cent.	. . . .	. . . .	4,320,000
Share in profits.	1,621,007	2,134,995	3,072,895
Carried forward	2,627,800	2,893,875	2,893,875

As to the company's activities, the directors say that a further number of branches of the works had to be rearranged, owing to war requirements. The sale of dyes, partly owing to stocks lying abroad, partly owing to added materials, has continued to a certain extent, also the making of nitrogen has further increased.

In this connection the Munich *Neueste Nachrichten* declares that, even if the final result is satisfactory, it should be borne in mind that the competition which has arisen, both in enemy and neutral countries, is profiting by the long duration of the war, and consequently the recovery of many former German markets abroad is rendered much more difficult, and, in any case, will be possible only by great efforts and at the cost of special sacrifices.

Reports of a recent raid by French military aviators along the upper Rhine are to the effect that the works of the "Badische" were destroyed by bombs early in July. No details are given. As the establishment covers such a vast area it seems improbable that more than a comparatively small portion of the plant could be put out of commission by the hurried efforts of an aeroplane squadron.

Export Licenses

The wording of the recent Proclamation, requiring export licenses for a variety of articles, is somewhat vague in regard to the chemicals which fall within its purview.

Upon the recommendation of the Exports Council the term "Explosives" is now stated to include the following chemicals:

"Ether, alcohol, sulphur, sulphuric acid and its salts, acetone, nitric acid and its salts, derivatives of benzol, phenol (carbolic acid) and its derivatives, derivatives of toluol, mercury and its salts, ammonia and its salts, glycerine, potash and its salts, all cyanides."

The derivatives of benzol, of toluol and of phenol form a decidedly extensive class, including most of the artificial dyestuffs now manufactured in the United States. To officials not familiar with the vocabulary, and with the nature of the various classes of compounds, coming into consideration, there will be no little difficulty in applying this rule, and in avoiding the danger of making it a serious handicap on the export of a number of coal-tar compounds non-susceptible of use as explosives or in the manufacture of explosives. A relatively very small list of derivatives would fall in the two categories, and they could easily be specified by name.

COAL-TAR CRUDES

The Determination of Phenol in Crude Carbolic Acid and Tar Oils*

By John Morris Weiss and C. R. Downs

INTRODUCTION

The purpose of this paper is to describe a method which is capable of giving accurate results for the determination of phenol in mixture with cresols, higher phenols, and neutral oils.

Many methods for the determination of phenol have been proposed. Most of these, however, are designed to serve as an assay of pharmaceutical phenol, and are of no value for the purposes which this paper is designed to cover.

Leube[1] used a colorimetric method with ferric chloride. Nietsch[2] converted the phenols into sulfonates, formed the barium and lead salts and made a determination of the metal content of these salts. Carre[3] converts the phenol to picric acid and makes a colorimetric determination. None of these methods are applicable for even an approximate assay of the real content of phenol in a crude acid or tar oil.

Warnes[4] gives three very empirical methods for testing carbolic acid. The results give only the melting point of a definite volume percentage fraction of the original acid, and though comparative between different samples, does not give any real indication of the actual amount of true phenol present.

Lunge[5] gives a table showing the lowering of the fusing points of mixtures of para-cresol and phenol according to tests made by Lunge and Zschokke. This table is patently useless for estimation purposes, as, in ordinary cases, meta- and ortho-cresols are also present in varying proportions, and affect the melting point to a very considerable degree.

Later Lunge[6] gives a method of examining crude phenols (carbolic acid) for its yield of crystallizable phenol of a melting point from 15.5 to 24° C. This is known as the method of Lowe, and was in use among English tar distillers for some time. The crude acid is fractionally distilled and the melting point taken on a definite per cent. by volume of the crude acids. The test is, however, more a specification for quality of crude acids than a method of analysis. Lunge further states that for the purpose of "acquiring good practice in this method" mixtures are made of various content of pure crystallized carbolic acid and of cresols (preferably tar cresols, *i. e.*, a mixture of the three isomers) and the melting points of these mixtures are previously determined. No account is taken of variation in melting point due to variation in the interproportion of the three cresols. As Lunge himself points out, the relative proportions of the three cresols in coal-tar are not constant. No attempt was made to take advantage of the differences in specific gravity between phenol and the cresols. The method is very crude and would give only very approximate results.

Stochmeier and Thurnauer[7] extract tar acids from carbolic oil, separate the hydrocarbons from the carbolate by steam distillation, liberate the tar acids and fractionate them. They then use Koppeschaar's bromination method[8] on the fractions, and use special factors for the fractions containing the cresols. The titration of such mixtures is clearly not allowable as shown by Vaubel.[9]

In 1912 one of the authors[10] made, perhaps, the first published attempt to develop a rational method for the estimation of phenol in crude carbolic acid and tar oils, and it is along the general lines of that method that the method given in the present paper was developed. The method was fairly accurate, giving results within about 10 per cent. of the phenol present. The range of the series of mixtures, however, was not close enough and the cresols available at that time were not quite so pure as today. Moreover, the recent increase in value of phenol has made a more accurate method necessary, whereas in the past the close determination of phenol was not of prime importance. In the present method the procedure has been considerably changed and amplified, and a much more complete series of mixtures of known composition has been prepared and studied.

Very recently, while this paper was in course of preparation, René Masse and M. H. Leroux[11] published a method which is in some respect very similar to the method submitted by the authors of this paper. We have taken the liberty of reproducing the determination curve (see Fig. I) given by them, in this paper, and plotting on it points as found in the examination of our own series of mixtures. At some points the error can be very great. They use solidification point alone for their determination, and with variation of the proportion of the cresols among themselves, there might be an error of 2.6 per cent. at the 75 per cent. point, of 1.8 per cent. at the 70 per cent. point and of 4.4 per cent. at the 65 per cent. point. This will be seen more clearly by a reference to the curve. Masse and Leroux used a mixture of 50 per cent. *o*-cresol and 50 per cent. of a mixture of 60:40 of meta- and para-cresols, for the basis of the determination. In

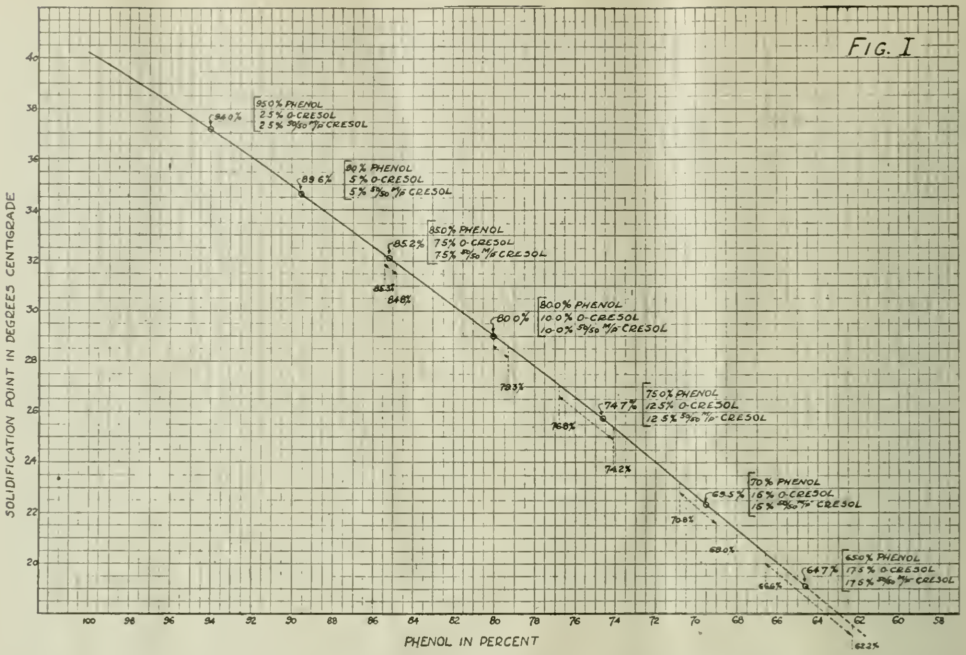

FIG. I

our work we used a 50:50 meta-para-cresol mixture (as naturally occurring in our oils) and varied the relation of the ortho-cresol to this. In the following table we have shown the variation in percentage between their curves and ours on the mixtures which correspond most closely to their proportions:

TABLE I.

Per cent Phenol	Per cent o-Cresol	Per cent m50/p50 Cresol	Per cent Variation
95	2.5	2.5	1.0
90	5.0	5.0	0.5
85	7.5	7.5	0.2
80	10.0	10.0	0.0
75	12.5	12.5	0.3
70	15.0	15.0	0.5
65	17.5	17.5	0.2

This shows their curve to be quite correct if the proportion of ortho-cresol to meta- and para-cresol be equal, but this is not generally true of tar oils. Therefore, the use of the simple solidification point curve is insufficient.

In general, their directions for the distillation of the liberated acids are fairly complete, as is also their description of the method for determination of the solidifying point of the fractions. There are, however, a number of points in the handling of tar acids to remove neutral oils, on which their directions are not explicit, and here there is considerable chance for the introduction of serious errors. These errors may be further increased in the procedure for the determination of the phenol content of a tar oil.

The physical properties of the cresols and of phenol have been variously given in the literature (see Table II).

There are numerous other single references dealing with single properties of these substances but it does not seem worth while to collate them here. We have ourselves made a considerable investigation on the true solidifying point of pure phenol and find it to be 40.5° C. In this we are confirmed by Eger.[12, 13] The differences in the literature are probably due to early tests being made on small samples by the capillary tube method which might give higher figures than our solidifying point tests taken on a much larger bulk of material. It is also probable that some of the other melting points given are taken on the same basis, although we have not investigated them to the same degree as we have in the case of phenol. A comparison of our method for solidifying point (see later) with the ordinary capillary tube melting point will indicate clearly how such differences might arise.

Experimental.

The authors have attempted to give the experi-

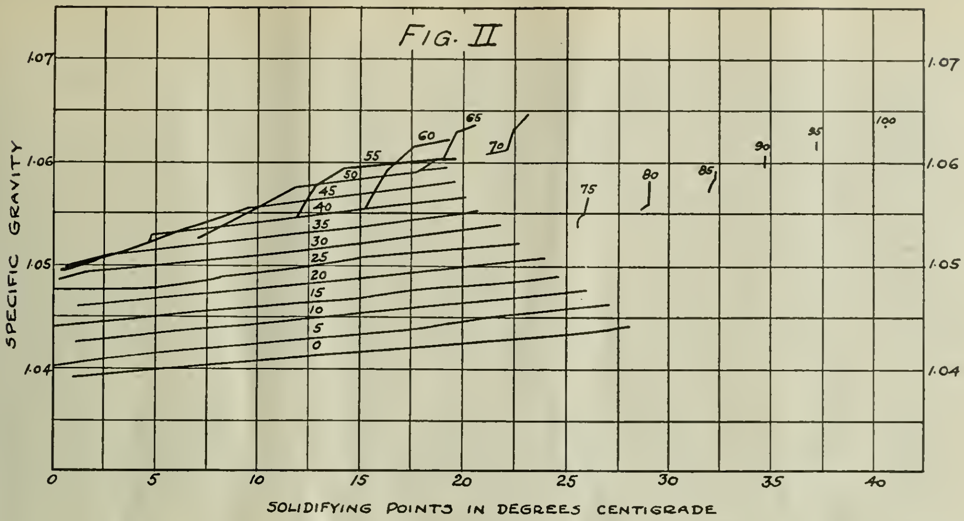
[13] Chem.-Ztg. Rep., **1903**, 86.



mental work in chronological order, inserting from time to time the conclusions drawn. We have not attempted to give all the details of manipulation in the single experiments, but have collected these together at the end in a description of the method. We wish to express at this point our appreciation of the work of H. E. Lloyd and C. J. Downey, who performed most of the laboratory work in connection with the problem.

A—Materials Used for Standard Mixtures.

(1) *Phenol* was prepared in the plant and represented a close cut middle fraction from the final distillation of synthetic phenol. It did not require further purification by the laboratory.

(2) *Ortho-Cresol*—We selected from a works run an *o*-cresol fraction of high purity, but containing some neutral oil and naphthalene. It was dissolved in caustic soda solution, the carbolate freed from neutral hydrocarbons by steam distillation and the cresol precipitated again by dilute sulfuric acid. The liberated cresol was separated and fractioned through a 3-bulb LeBel-Henninger column, cutting so as to give a cresol of a boiling point of about 2° C.

(3) *Meta-Para-Cresol* was prepared in the same way as the *ortho*-cresol from another fraction obtained similarly. The final material was shown by the Raschig nitration test to contain 49.3 per cent. *meta*-cresol and 50.7 per cent. *para*-cresol.

The three materials as finally used in the mixtures showed the constants given in Table III.

TABLE III.

	Solidification Point	Specific Gravity at 25° C./25° C.	Boiling Point Range
Phenol	40.4° C.	1.0636(a)	180-182° C.
o-Cresol	29.0° C.	1.0144	189-191° C.
m-p-Cresol	Below 0° C.	1.0339	199-201° C.

(a) Taken at 45°/45°C.

B—Mixture of Pure Materials.

Twenty-one so-called series were made up, using from 0 to 100 per cent. of phenol, each series representing a 5 per cent. phenol increment. In the series themselves the relative proportions of the *o*-cresol and the *m-p*-cresol were varied for every even 5 per cent. This involved making and testing a total of 231 mixtures.

The mixtures were made up by weight and the accuracy of the weighings was such as to make a maximum possible error in the final percentage of the material in the mixture of not over ± 0.2 per cent. Proper precautions were taken to prevent absorption of water both in making up the mixtures and in subsequent handling of them. The mixtures were then subjected to various physical tests as described below.

(1) *Bulb Distillation*—The first few mixtures were submitted to this test, but it was soon found that sufficiently concordant results could not be obtained. It was necessary to have accurate readings of percentages distilled every even degree in order to differentiate between mixtures made over such a close range as these were. There were so many factors, such as barometric pressure, emergent stem corrections, thermometer lag, rate of distillation, effect of air currents, etc., any of which could produce an error as great or nearly as great as 1° C., that the authors decided it to be utterly impractical to use boiling point ranges as a method of differentiation. After a number of tests had indicated the hopelessness of this method of attack it was definitely abandoned.

(2) *Refractive Indices*—A few preliminary tests on the components of the mixtures showed definitely that their constants were too close to enable us to determine at all accurately the character of a mixture by this means.

(3) *Specific Gravity*—This test proved very useful and was adopted for general use. The details of carrying out this test will be given later in connection with the described testing method. It was found desirable

(a) The values for the specific gravity given in this column are plotted on Fig. IV.

(b) These values are plotted on Fig. II because if plotted at 45/45° C, the curve for 70 per cent phenol would interfere with the other curves in this figure.

to use two standard temperatures. The mixtures having a solidifying point less than 25° C. were taken at 25° C. compared to water at 25° C. Above this point the specific gravities were taken at 45° C. compared with water at 45° C. Occasionally a mixture test will be found where the solidifying point is 25° C. or a trifle higher and still the specific gravities given as of 25° C.—for all these cases the specific gravity was never taken in the solid state or by correction from a higher temperature, but represents an actual determination in the supercooled liquid.

(4) *Solidifying Point*—The old method used ordinarily for phenol, in which the thermometer is used as the stirring rod in the test tube, was given a thorough trial and proved to be too inaccurate, in so far as checks by different operators were concerned, to be used for the present purposes. Accordingly a modified method was devised, the details of which are given later under the testing method. This modification of the method was used throughout the work presented in this paper.

(5) *Detailed Tests*—These are shown in Table IV. The curves in Figs. II, III and IV bring out graphically important features of these tests.

(6) *Consideration of Results*—In Fig. II there are plotted curves of all mixtures, where the solidifying point is above 0° C., using the solidifying points as ordinates and the specific gravities as abscissas and plotting a curve for each 5 per cent. of phenol. It is evident from an examination of the detailed results in the tables that if a solidifying point of a mixture is indeterminate, that is, below 0° C., that the specific gravity alone is not sufficient data for an exact determination. Therefore, for determination of phenol by this method it is first necessary to concentrate the phenol into a fraction containing only phenol and cresols of such a nature that the solidifying point is above 0° C.

It will be further noted in Fig. II that, from 0 to 30 per cent. of phenol, the curves are well separated and the constants of a mixture will serve for exact quantitative determination. From 30 to 70 per cent. phenol, the curves cross each other irregularly and points in this area are indeterminate and, therefore, not susceptible of exact determination. From 70 to 100 per cent. phenol the curves are well separated and this area can be considered as determinate. The two determinate areas are shown on a larger scale in Figs. III and IV. It is, therefore, evident that to determine phenol, it will be necessary to bring it into a fraction containing only phenol and cresols of such composition that its physical constants will plot to a point within one or the other of the determinate areas shown. The first portion of the remaining problem was, therefore, to develop a method of fractional distillation which would separate all the phenol from a crude acid with only cresols as an impurity. It is evident that with such a fraction, if its constants do not throw it into the determinate area, that a mixture of the fraction with a known amount of *pure phenol* can be made, which mixtures can

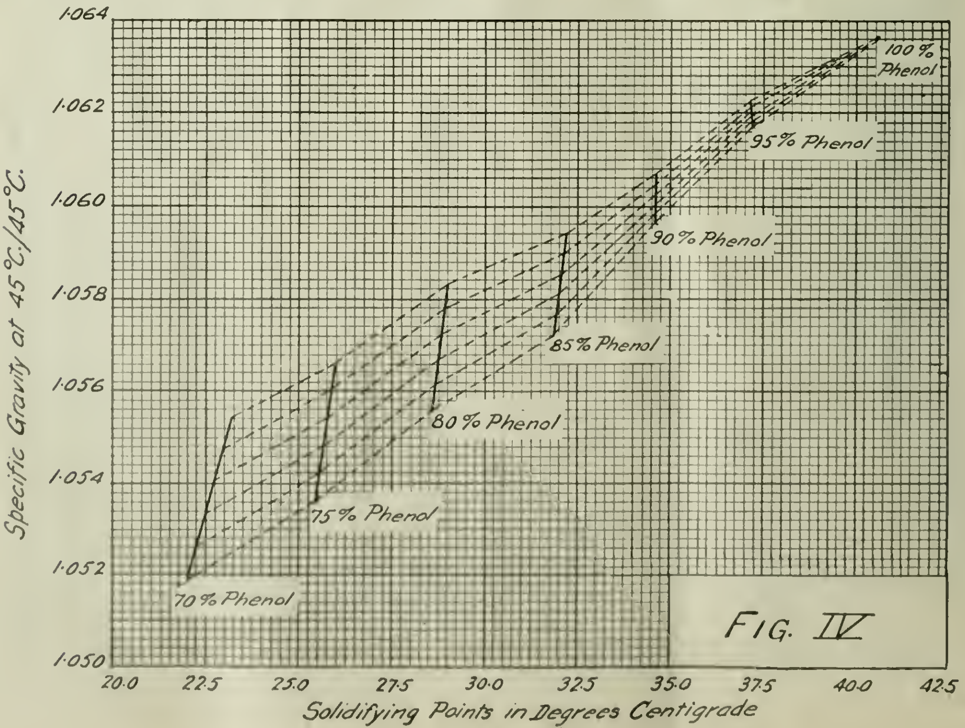

FIG. IV

be made to fall in one of the determinate areas. The percentage of phenol can be readily determined in the mixture and from the knowledge of the amount of phenol added, the percentage of phenol in the original fraction can be readily deduced. With this then as a basis, work was commenced on known mixtures of phenol, cresols, higher acids and oils to perfect the manipulative details necessary to bring phenol, no matter what its form, quantitatively into a fraction in which it was accompanied by cresols alone.

C—Work on Known Mixtures to Perfect the Details of the Method.

The preliminary tests involved a comparison of the Hempel and the LeBel-Henninger fractioning tubes. The Hempel tube was of the standard Barrett type (A. H. T. Cat. No. 20496) and the LeBel, the 3-bulb variety: 6-bulb LeBels were tried, but those obtainable were not of sufficiently good workmanship to withstand the required temperature without cracking. For these preliminary tests it was necessary to prepare some phenol-free acids of a boiling point above cresols. This was done by taking ordinary crude acids, removing the oil and naphthalene, and fractioning, taking for use the fraction distilling above 200° C. It was shown by careful test to be free of phenol. In these preliminary tests the acids (free of oil and naphthalene) were fractioned and cut at 190 and 202°. The 190-202° fraction was redistilled and cut at 197° C. The total fraction below 197° C. was compared with the curves and the phenol content estimated. If necessary, a suitable mixture was made with pure phenol so as to bring the mixture into the determinative range. Needless to say, all details of the distillation were gravimetrically quantitative.

Tests 1 to 7 may be tabulated as follows:

Test No.	Mixture—Percentages Phenol	o-Cresol	m-p-Cresol	Per cent Higher Acids	Per cent Phenol Recovered	Error in Per cent of Phenol Present
1	33.3	....	....	66.7	32.2	—3.3
2(a)	20.0	20.0	26.0	40.0	16.0	—20.0
3	20.0	20.0	20.0	40 0	19.2	—4.0
4	10.0	15.0	15.0	60.0	10.4	+4.0
5	50.0	10.0	10.0	30.0	48.0	—4.0
6	25.0	25.0	25.0	25.0	24.2	—3.2
7	30.0	5.0	5.0	60.0	29.5	—1.7

(a) In this test the Hempel column waa used, in all others the LeBel was used.

After these tests we decided to abandon the Hempel distillation for this purpose and until otherwise noted all tests were run using the LeBel 3-bulb column. A comparison of the bulb distillation of the "to 197°" fraction of Tests 2 and 3 shows why Test 2 was so much further off than Test 3.

BULB DISTILLATIONS OF TESTS 2 AND 3.

	187°	190°	195°	200°	Dry at
Test 2	2	22	81	91	205° C.
Test 3	1	47	90	98	203°.C.

The Hempel had not removed xylenols as well as had the LeBel. The effect of xylenols would be to lower the specific gravity without proportionally lowering the solidifying point, thus giving a lower phenol indication than the truth. This is true to a lesser degree in the LeBel tests and is doubtless the cause of the somewhat low results obtained in a number of the tests. In fact, on Tests 1 to 7, the only ones where bulb distillations were made on the "to 197°" fraction, all showed some residue above 201° C. It has not been thought worth while to record these distillations in detail, as all the essential information is given in the two already shown.

At this point of the investigation we decided that the fractioning method was fairly accurate, though not entirely satisfactory. It was considered advisable now to proceed to oil mixtures to determine the points in this phase of the investigation which required our attention.

Test 8—For this test we prepared a quantity of acid-free oil by completely extracting ordinary creosote oil with caustic soda. A mixture was made by using 85 per cent. of this oil and 15 per cent. of acids containing 20 per cent. phenol. The acids were extracted by caustic soda solution from a portion of this mixture. The carbolate was steam-distilled to remove neutral oils and naphthalene, the acids liberated by dilute sulfuric acid and carefully separated from the sodium sulfate layer. The test was then carried on in the usual way, taking care to separate all water from the "to 197°" fraction

The phenol recovered showed an error amounting to -20 per cent. of the phenol present.

Test 9—Here we used 80 per cent. of oil and 20 per cent. of acids containing 20 per cent. of phenol. The carbolate was formed as in Test 8, and washed with 600 cc. of benzol in three 200-cc. portions. The united benzol washings were agitated with 100 cc. of water in two 50 cc. portions. These were added to the carbolate, which was then boiled gently to expel any benzol present. The sulfate liquor, after acidification, was not washed for recovery of acids.

The general method of fractioning, which was adhered to except where otherwise noted, was to distil to 170°, separate acids from water in the distillate and return the former to the distilling flask. Fractions were then taken to 190° C. The second fraction was redistilled collecting to 197° C. and combining all acid distillates up to 197° for test. The recovery of phenol showed a loss of 22.1 per cent. of the phenol present.

Test 10—In this test no change was made in the relative proportions of the acids and neutral oil. The carbolate was steam-distilled. The NaOH solution was added in three 210-cc. portions. The sulfate liquor was washed with 150 cc. of benzol in three 50-cc. portions and these washings were added to the liberated acids. The mixture used was the same as in Test 9. The error amounted to a loss of 21.7 per cent. of the phenol.

The residual acids after fractionation were combined and tested for phenol, but none was found. In this test the benzol was separated from the acids in the fractionation. The benzol recovered had an acid odor, but only a trace of acids could be recovered by solution in NaOH.

The results of Tests 9 and 10 showed that the tar oils and naphthalene in the carbolate may be removed with benzol, instead of steam distillation.

Test 11—In this test the acid-oil mixture was approximately the same as in the previous tests. The method of procedure was the same as in the previous test, except that the liberated acids were washed with 200 cc. of a saturated NaCl solution for removal of sulfate liquor. The solidifying point of the acid mixture made on fractionation of the acids was so low that no further data were taken.

Test 12—This test in conjunction with Test 14 was made in order to determine the loss due to solution of acids in the sulfate liquor. In the light of further tests, however, it does not indicate much. This is due to other greater losses which had not been discovered at this time. No neutral oil was used in the mixture.

The carbolate was formed using 125 per cent. of the theoretical NaOH necessary. The acids were liberated with 50 per cent. H_2SO_4. The sulfate liquor was washed with 150 cc. benzol in 50-cc. portions and the recovered acids fractionated. An acid containing 20 per cent. of the phenol was taken. The error amounted to -8.5 per cent. of the phenol present.

Test 13—In this test the new modifications were the weakening of the H_2SO_4 to 33⅓ per cent. and the washing of the extracted oil with an additional 100 cc. of NaOH solution (making a total of 140 per cent.). Benzol was used to wash the carbolate. The sulfate liquor was agitated with 125 cc. of benzol and the washings added to the main quantity of acids. The acids were fractionated in the LeBel-Henninger column. The same mixture was used as in Test 12. The error found was -13.2 per cent. of the phenol present.

Test 14 was made in order to compare the loss of phenol with the loss in Test 12, where a carbolate was made and the acids liberated. The mixture contained no oil and was simply fractionated in the LeBel column. Here the error was -8 per cent. of the phenol present.

The results of this test would indicate that the loss in recovery from a carbolate was not much.

Test 15 was made in order to check the curve with a mixture containing 20 per cent. of phenol.

Mixture No. 1	Pure Phenol	20.15 g.
	Pure o-Cresol	40.05 g.
	Pure *m-p*-Cresol	40.05 g.
Mixture No. 2	Pure Phenol	75.00 g.
	Mixture No. 1	25.00 g.
Solidification Point of Mixture No. 2		28.8° C.
Specific Gravity (15/15 C.) of Mixture No. 2		1.057
Phenol in Mixture No. 2		80%
Phenol in Mixture No. 1		20%

This shows the curves to be correct at this point.

Test 16—In view of the results of tests to this point it was thought that a considerable part of our losses was due to fractionation and that a change in the temperature at which the fractions were cut might help in the phenol recovery. Accordingly a mixture of acids was made and fractionated using the LeBel-Henninger column as in previous tests. The first fraction collected was to 190° C., the second between 190 and 205° C. This second fraction was redistilled until a temperature of 198° C. was reached. The first and redistilled fractions were collected in the same flask as in previous test. Using the usual 20 per cent. phenol acid, an error of -16.5 per cent. of the phenol present was obtained.

Test 17—In this test the temperature of fractionation was again changed. The first fraction collected was that coming over to 190° C.; the second between 190 and 204° C. This fraction was redistilled up to 195° C. With the same mixture as in Test 16 we showed an error of −10.1 per cent. of the phenol present.

Changing the temperature of fractionation did not increase the amount of phenol recovered. We then concluded that the column used in fractionation should be changed.

Test 18—We then decided to try the 12-pear column. To determine the efficiency of this apparatus as a fractioning device, we made a mixture of pure acids as in previous tests, and fractionated the mixture using the original temperature, *i. e.*, to 190° C. (190-202° C.) and redistillation to 197° C. The error here amounted to only +1.4 per cent. of the phenol present.

Results of this test showed that the losses due to faulty fractionation had been overcome. From this point on, our tests were made with a view to overcoming the losses which occur on formation of carbolate and subsequent liberation of the acids. This involved the proper strength and amount of H_2SO_4, the temperature of acidification, the washing of carbolate and recovery of the acids dissolved in the sulphate liquors.

Test 19—In this test we attempted to recover all of the phenol in a pure acid mixture after converting the acids to a carbolate. The acids were agitated with 125 per cent. of the theoretical amount of NaOH necessary. The acids were then liberated with 25 per cent. solution of H_2SO_4, using a very slight excess of acid (about 10 cc.). The sulphate liquor was washed with 100 cc. of ether in two 50-cc. portions and the washings added to the main quantity of acids. The acids were then fractionated with the 12-pear column. It was impossible to make a clear separation of the ether and acid distillates. The ether and water that came over were agitated with an NaOH solution and the acids recovered. They amounted to about 4 cc. However, they were not added to the acid distillate and so were lost. Better results were obtained here by reducing the strength of the sulphuric acid to 25 per cent. There was a cleaner separation, the acids were lighter colored and there was no gas formation. The error here was −2.1 per cent. of the phenol present.

The results of this test indicated that the phenol in a mixture of pure acids could be recovered substantially quantitatively from a carbolate.

Test 20—In this case 150 per cent. of the theoretical quantity of NaOH was used to form the carbolate. The sulphate liquors were washed with benzol. Any acid was recovered from the benzol by washing with caustic soda as described previously. This acid was added to the main bulk of acids. The recovery of phenol showed a very low error, only 0.2 per cent. of that present.

Test 21 was made using a mixture of 20 per cent. of pure phenol with crude cresols and higher acids, instead of the purified acids, as in Tests 19 and 20. 125 per cent. of the theoretical amount of NaOH was used. The carbolate was washed with 500 cc. benzol in 125-cc. portions. The acids were recovered from the sulphate liquor as in Test 20. The error was −1.3 per cent. of the phenol present.

Test 22 was a check on Test 20, the same procedure being used in each test. The error here was −0.8 per cent. of the phenol present.

After running Tests 20, 21 and 22, we concluded that the phenol present in a mixture of acids with small amounts of oil could be recovered with but slight loss. Our next attempt was to recover the phenol from an acid-oil mixture which contained a large amount of neutral oil.

Test 23—In this test we added enough neutral oil to the acids to make it 80 per cent. of the total mixture and attempted to recover the phenol. The acids were extracted from the mixture with 150 per cent. of the theoretical amount of a 20 per cent. NaOH solution: 800 cc. of the NaOH solution were used in three 200-cc. and two 100-cc. portions. The carbolate was washed with 500 cc. of benzol in 100-cc. portions. The sulphate liquor was washed with ether, and the dissolved acids recovered from ethereal solution with a weak NaOH solution and added, after liberating with H_2SO_4, to the main quantity; 9.2 grams were recovered. This method of recovery and separation from the solvent is a new and important step in the process. The acids were fractionated as before.

Acid-Oil Mixture	Phenol	59.85 grams 20%	20 per cent
	o-Cresol	59.80 grams 20%	
	m-*p*-Cresol	59.80 grams 20%	
	Higher Acids	119.30 grams 40%	
Neutral Oil		1212.50	80 per cent

In the above mixture the acids, with the exception of the phenol, were crude.

The loss of phenol in this test (*Nvf p*er cent. of the phenol present) was very high (due to imperfect technique, as will be seen later), and it was decided to make tests using smaller quantities of neutral oil.

From this point on, the general method of recovery of the acids was the same, *i. e.*, formation of a carbolate with NaOH (20 per cent. strength), washing of the carbolate with pure benzol, washing the benzol solution of carbolate with water, boiling of the carbolate, liberation of the acids with 25 per cent. H_2SO_4, washing the sulphate liquors with benzol and recovery of the dissolved acid with weak (10 per cent.) solution of NaOH. All fractionations were made with the pear column.

The essential results of Tests 24 to 35 inclusive are shown in the following table:

Test No.	Grams Phenol	Grams *o*-Cresol	Grams *m*-*p*-Cresol	Grams Higher Acids	Grams Oil	Grams Phenol Recovered	Error in % Phenol Present
24	59.75	60.00	60.35	119.90	101.75	55.83	—6.6
25	59.20	59.75	59.85	119.70	10.10	58.08	—1.8
26	60.00	60.10	60.00	119.60	10.30	63.10	+5.1
27	60.00	59.61	59.70	119.10	30.00	60.08	+0.13
28	58.55	60.00	59.60	119.70	120.00	58.10	—0.8
29	29.56	70.00	70.00	129.30	......	31.20	+5.2
30	29.40	70.30	69.70	129.30	......	29.80	+1.6
31	14.65	75.00	74.80	134.70	......	14.05	—4.1
32	15.05	76.00	74.80	135.15	......	15.90	+7.0
33	88.55	44.90	45.10	119.70	......	82.30	—7.0
34	149.90	30.05	29.65	90.15	......	149.20	—0.5
35	**15.05**	74.85	75.50	134.80	1200.00	14.73	—2.1

In Test 33 a known loss occurred in manipulation, so that this result is natural. The tests seemed to us to be accurate enough for all practical purposes, and checks should be obtained to 0.8 gram of phenol if the work is carried on carefully and conscientiously.

Up to this point we had succeeded in the recovery of the phenol from its mixtures with other pure acids, with unpurified acids in varying portions, and with neutral oil in varying proportions.

To determine the reliability of the test, when applied to crude carbolic acid, we first determined the percentage of phenol in a sample of ordinary crude acids, and next in these acids to which we had added a known amount of pure phenol.

Test 36—*Determination of the phenol in ordinary crude carbolic acid:* The acids contained 5.32 per cent. (by weight) of water and had a specific gravity at 15.5° C. of 1.072.

We first tried to wash a carbolate made with the crude acids as obtained, but there was not a clean separation of the benzol and carbolate layers. We found it necessary to distil the acids first. The crude acids were distilled, after weighing, directly into a 2000 cc. separatory funnel.

Weight of acids distilled........................	301.5 grams
Weight of distillate (by difference)..........	271.3 grams—90 per cent
Black pitch residue..............................	30.2 grams

The carbolate was now formed as in previous tests, and washed with benzol. The recovery of the acids and the fractionation were carried out as in the previous tests. We found the phenol content by weight to be 16 per cent. on the dry acids or 15.14 per cent. on the wet acids.

Test 37—In this test we added a known amount of pure phenol to the crude acids tested above.

Crude acids....................	301.15 grams
Pure phenol added...........	15.85 grams

On determination of the phenol we found that of the phenol added we had recovered 99.2 per cent.

The better results in the later tests were due to constant improvments in the technique with experience. In the following description, we believe, we have given that technique with sufficient wealth of detail to enable any operator following directions carefully, to obtain consistent, accurate results.

D—Standard Method for Determination of Phenol in Crude Carbolic Acid and Tar Oils.

I. Preface—In this test extreme care and faithful attention to details are necessary to secure accurate results. All instructions given are the epitomized result of considerable experience and are not given arbitrarily, but with a purpose. The test has been a difficult one to develop and requires greater care and skill than do the ordinary tar-testing methods. Even a slight deviation from the directions can cause serious discrepancies.

II. Preparation of the Oil—If the oil is at all dirty, so that the subsequent separation of the carbolate will not be clean, it must be distilled. This shall be accomplished by weighing a suitable quantity of oil into a clean copper tar-still and taking the total distillate from the start of distillation to coking. The amount of total distillate by weight shall be noted so that results may be figured back to the original oil if desirable. If any foaming-over occurs during the distillation, the run must be rejected and a new one undertaken.

III. Extraction of the Acids From the Oil—The approximate percentage of tar acids in the oil should be determined by a rough test. A weight of oil which contains between 300 and 350 g. of acids shall be placed in a separatory funnel and treated with 300 cc. (approximate) of 20 per cent. caustic soda solution; this caustic soda solution may be made from commercial caustic soda. The oil and caustic soda shall be given a thorough mixing by shaking, care being taken to prevent mechanical loss. The mass shall now be allowed to stand until the carbolate settles completely and a sharp line of division appears between the oil and the carbolate. With a properly distilled oil, from 15 to 30 minutes should suffice. If the oil contains solids, it shall be warmed before extraction to a temperature sufficient to keep solids in solution, and while settling be suspended in a bath of like temperature.

After settling is complete, the carbolate shall be separated and brought into another separatory funnel. The oil shall be washed successively with three more portions of 200 cc. each of the same caustic soda solution, observing the same precautions as to agitation, settling and separation. These separated soda solutions are to be added to the first carbolate. On the last separation it is better to run a few drops of oil along with the carbolate, rather than leave a few drops of carbolate in the oil. After this treatment the oil shall be tested to determine if it is free from tar acids and if so, it may be discarded.

Note—If crude acids, not oil, are to be tested, 300 to 350 g. of the crude acid shall be taken in a separatory funnel and dissolved in 800 cc. of 20 per cent. caustic soda solution. The treatment from this point on is the same as with carbolate extracted from oil. If the crude acids are tarry it is advisable to distil them quantitatively before dissolving them in caustic soda.

IV. Purification of the Carbolate—The carbolate in a separatory funnel shall be extracted five times successively with 100-cc. portions of pure benzol. The manipulation shall be: Add the benzol to the carbolate, mix thoroughly by shaking and allow to settle. Draw the carbolate into another separatory funnel and draw the benzol into a third separatory funnel. Repeat the agitation with fresh benzol four times more, using the two original separatory funnels for this purpose. Finally, after running the washed carbolate into a beaker, rinse each of the funnels which contained carbolate, twice, with 25 cc. each of water, and add the water to the carbolate in the beaker. Take the third separatory funnel, which contains the combined benzol, and wash twice with 50 cc. of water, adding this water also to the carbolate in the beaker. Bring the carbolate in the beaker to a gentle boil until the odor of benzol disappears. No odor of creosote shall be evident in the carbolate at this point. If such odor appears, the washing has not been properly carried out and must be repeated. The carbolate purified of oil is ready for acidification after cooling. The benzol used for extraction may be discarded.

V. Acidification—The purified carbolate shall be placed in a separatory funnel and acidified with sulphuric acid of 25 per cent. strength (sp. gr. 1.21 at 15.5° C.). The beaker containing the carbolate shall be rinsed with water and the rinsings added to the carbolate in the funnel. During acidification the mass *must* be kept *below 40° C.* by immersion in a bath of cold water. Test for acidity should be made from time to time with litmus paper. *More than a very slight excess* of acid (5 to 10 cc.) must not be added after litmus shows a red color. When acidification is complete, the funnel shall be allowed to stand until complete separation has taken place and the lower layer of sodium sulphate solution is perfectly clear or at most shows a slight opalescence. This settling requires from 3 to 4 hours. After settling is complete the sulphate layer shall be drawn off and kept for further treatment. The carefully separated acid layer shall be drawn down into a weighed 500 cc. round-bottomed short ring neck flask and kept there until further treatment.

VI. Treatment of the Sulphate Solution—This shall be returned to the separatory funnel which contained the separated tar acids, which still has a thin film of tar acids adhering to the walls. The sulphate liquor shall be extracted three times with successive portions of 100 cc. each of pure benzol and the benzol extracts combined in a separatory funnel of about 500 cc. capacity. The benzol extract shall now be extracted with two successive portions of 25 cc. each of 20 per cent. caustic soda solution, or until the soda solution separates nearly colorless. The benzol can then be discarded. The caustic soda solution shall then be warmed until all odor of benzol disappears and acidified with enough 25 per cent. sulphuric acid to make slightly acid. This shall be allowed to settle completely, the lower layer of sulphate drawn off and discarded, and the upper layer of acids added to the flask containing the main amount of the separated acid. This flask shall now be weighed and the weight of *wet* crude acids recorded.

VII. Fractional Distillation—*A. Column*—This shall be the standard 12-pear still head (Eimer & Amend catalogue No. 7156).

B. Flask—This shall be a short neck flask as described under V.

C. Condenser—This shall be the regular Barrett trough type with a 24-in. tube (A. H. T. catalogue No. 20432).

*D. Thermometer**—This shall conform to the following specifications: (1) It shall be graduated from 170 to 225° C. in 1/5° C. and shall be accurate at total immersion to 1/5° C. (2) It shall be well annealed and shall conform to the following dimensions:

Total length—less than 380 mm.
Bulb length—20-25 mm.
170° mark to bottom of bulb—70-80 mm.
Scale length 170-225°—270-280 mm.
Stem diameter—5-7 mm.
Bulb diameter—4-5.5 mm.

E. Setting Up Apparatus—The flask shall be supported over a burner on a 6-in. square of 1/4 in. asbestos board with an opening in the center 3.5 in. in diameter. It shall be surrounded by a circular asbestos shield about 3½ in. high and of such diameter as to enclose the flask. A piece of asbestos with a hole cut for the neck of the flask forms the top of the shield. The pear column shall be connected to the flask by a tight-fitting cork, and the condenser to the side tube of the pear column. The thermometer shall be inserted into the top of the pear column by means of a well-fitting cork in such manner that the top of the thermometer bulb is opposite the middle of the off-take of the column. The condenser trough shall be kept full of cold water.

---

*This thermometer can be obtained from the Taylor Instrument Co.

F. Method of Conducting the Distillation—The apparatus shall be set up as described and the distillation started and continued at the rate of one drop per second. The distillate shall be first caught in a 100-cc. separatory funnel until the temperature has reached 170° C. The distillation shall then be interrupted and sufficient salt added to the contents of the separatory funnel to cause any acids coming over with the water to rise to the surface. The aqueous layer is removed and the acids returned to the distillation flask, and the flask with contents weighed. Thereby the weight of *dry* acids is recorded. The distillation shall be again started and the first few drops of acid and water coming over collected in a small, dry separatory funnel. When the last drop of water is over, a fraction to 190° C. is collected in a weighed flask, which shall be closed by a cork as soon as the distillation is completed. The few drops of acid and water which have been collected in the small funnel shall be separated and the acid layer added to the distillate to 190° C. A second fraction from 190 to 202° shall be collected in a 250-cc. round-bottom, short ring-neck flask, which need not be weighed. The distillation shall be discontinued at 202° C. and the flask containing the 190–202° fraction shall be substituted for the first flask, which contained the crude acids. This fraction is now redistilled after drying the condenser tube, using the weighed flask containing the —190° fraction from the first distillate as a receiver. The distillation shall be carried to 197° C. The receiver which now contains the combined fraction up to 197° shall be weighed, the weight of the fraction recorded, and the receiver kept tightly stoppered.

G. Testing the Fraction—The fraction shall be tested for specific gravity and solidifying point as follows:

(1) *Solidifying Point:* A test tube 1 in. inside diameter (this dimension bears no deviation) and 5 in. to 6 in. long is held by a clamp in a vertical position with 3 in. of its lower end immersed in a 500–600-cc. beaker full of water. A standard 0–80° melting point thermometer (A. H. T. Cat. No. 20476), calibrated to an accuracy of *at least* 0.1° C., is fastened rigidly by another clamp in the center of the test tube with the bottom of the bulb 0.5 in. from the bottom of the test tube. An agitator, composed of an iron washer attached to a wire and arranged to work freely up and down the test tube around the thermometer, completes the outfit.

The fraction to be tested for solidifying point shall be poured into the tube to a depth of 2 in. and an approximate solidifying point taken. The contents of the tube shall be again liquefied and the outside bath adjusted to a temperature 4.5 to 5.5° C. below the approximate solidifying point. The temperature relation is very important. The sample is now allowed to cool with constant stirring. The temperature of the sample falls, but when crystals begin to separate a rise is noted which soon reaches a maximum where it remains constant for a varying period of time. This maximum temperature shall be taken as the solidifying point. Two successive tests must give identical results and care must be taken to keep the relation between solidifying point and bath temperature within the 4.5 to 5.5° C. range.

(2) *Specific Gravity*—If the solidifying point is 25° C. or less, this shall be taken at 25/25 C.; if greater than 25° C., the specific gravity shall be taken at 45/45° C. The specific gravities shall be taken with a Westphal balance. Most of the instruments supplied in the United States are standardized for 15.5– C. The balance is set up and the plummet should exactly counterpoise the arm when swinging freely in air. It must must be first adjusted to this condition by means of the leveling screw on the base of the column of the balance. The plummet is then immersed in freshly boiled distilled water at 1.5° C. and if the balance and weights are properly made a reading of 1,000 should be obtained. Next, a reading is taken in boiled distilled water at either 25 or 45° C., depending on the temperature desired. After the first adjustment of the balance, the reading in water at 15.5 C. may be dispensed with, but care should be taken to see that the balance in air is correct before readings are made. After the water standard at 25 or 45° C. is established, a reading is taken in the acid fraction at the same temperature. A simple division gives the specific gravity. Precautions to be observed are: keep the balance clean and dry; see that the plummet is properly cleaned and dried when changing from one liquid to another; keep the point to which the wire holding the plummet is immersed constant; control the temperature carefully; and see that the plummet swings freely and does not touch the sides of the vessel containing the liquid.

(3) *Comparison with Curves*—After the solidifying point and specific gravity of the fraction are determined, compare them with the phenol determination curves and see whether the point plotted by the constants falls well within a determination area. If it does not or if it is very close to the limit, it is best to proceed to make a mixture of the fraction with pure phenol.

(4) *Mixture with Phenol*—Phenol for this purpose must possess a solidifying point of at least 40.5° C., tested on the thoroughly dry material. A little judgment is required in making the mixture so as to use

the least amount of phenol which will bring the tests of the mixture well within one or the other of the determinate ranges. Needless to say, the mixture must be strictly quantitative, and must be made in perfectly dry containers. The mixtures are made up until one susceptible of determination is obtained. The specific gravities and solidifying points are taken exactly as described previously.

H. Interpretation of Results—After the tests show the point to be within the determinative areas the method of interpolation is as follows: If the plotted point occurs in the lower set of curves a line is drawn through the point normal to the curves between which it lies. The distance from curve to curve is measured accurately along this line and the fractional distance of the point is interpolated into per cent. phenol. If the point occurs in the upper set of curves, the line is drawn through the point parallel to the nearest of the dotted converging lines, the linear distance measured and the percentage interpolated as before.

If mixtures are made, the calculations are somewhat complicated and the following formula may be used:

Let A = per cent phenol found in mixture
B = Grams "to 197°" fraction taken
C = Grams pure phenol taken
X = per cent. phenol in "to 197°" fraction.

$$X = \frac{A(B + C) - 100\,C}{B}$$

The per cent. phenol in the "to 197°" fraction multiplied by the weight of the fraction gives the weight of total phenol in the oil or crude acid taken.

A specimen test on acid with the recorded data may be shown as follows:

Distilled 170—190°	60.65 g.	
190—202°	178.05 g.	
190—202° redistilled to 197°	78.05 g.	
Total under 197°	.138.7 g. = 46.2 per cent	
Sp. gr. at 25/25° C.		1.0602
Solidifying point		20.4°
Mixture to 197° fraction	25 g.	
Pure phenol	25 g.	
Sp. gr. at 45/45° C.		1.0576
Solodifying point		31.7° C.
Phenol in fraction mixture (from curve)		84.75 per cent
Phenol in original acids (calculated)		32.2 per cent

The method requires about two days to complete a test but several can be run simultaneously. The keynote of success in this work is extremely careful and accurate attention to the details of manipulation. This test has been in use in our laboratories since the early part of 1916, and has given very satisfactory results.

Research Department, The Barrett Company, 17 Battery Place, New York City

COAL-TAR INTERMEDIATES

Differentiation of the Two Naphthols by the Aid of Sulfotitanium.

G. Deniges (Anal. Chim. anal., 1916, 216, Annales de.fals., 1916, 90, 478) shows that a-naphthol and b-naphthol can be clearly differentiated, under certain conditions, by the sulfotitanium reagent, which has already been applied to the alkaloids. To 2-3 c.c. of the reagent in a test-tube, 1-2 centigrams of naphthol are added. On shaking, the mixture is colored intense green by a-naphthol, and blood red by b-naphthol. Dilution with acetic acid changes the first coloration to red-violet, but does not affect the second.

In another method of applying the test the same quantity of naphthol is dissolved in 10-20 drops of acetic acid, and 2-3 c.c. of the titanium reagent are carefully poured down the side of the test-tube. The reagent falls to the bottom, and at the zone of separation between the two liquids, especially if shaken gently, a green ring soon appears surmounted by a red-violet cloud, with a-naphthol, and a red ring, with the same color above, in the case of the beta compound. On thoroughly mixing the two liquids the color is distributed throughout. Naphthol ethers, such as the benzoates, react in a corresponding manner.

Manufacture of Phosgene.

Such large amounts of phosgene are now currently required for the production of Michler's ketone (resultant from the reaction of carbonyl chloride upon dimethyl-aniline) that a new method for preparing the same, recently devised by Norman L. G. Whitehouse, of Pittsburgh, Pa., possesses some interest (Amer. Pat. 1,231,226, of June 26, 1917). The essential feature is the introduction of carbon monoxide at the bottom of a cylinder containing liquid chlorine, which is maintained at a temperature of 34° C. The operation is continued until the absorption of the CO ceases. The ordinary method of preparing carbonyl chloride is to pass equal volumes of CO and Cl over a condensing surface such as animal charcoal or platinized asbestos.

Quantitative Estimation of Picric Acid.

A. A. Boon and James Ogilvie (Pharm. J., 1916, 97, 213) effect the determination of picric acid by quantitative reduction to the triamino compound. They use $TiCl_3$ and HCl, following the Knecht and Hibbert method, which gives accurate results, is sensitive, and may be applied to acid and alkaline solutions and to preparations containing camphor. The titration of picric acid with $N/2$ NaOH is limited in application.

3-Nitro-1-amino-benzene-6-sulfonic Acid.

The Bayer Co. (Ger. Pat. 294,547) describes a method for obtaining this intermediate by the action of oleum, in excess, on m-nitraniline at 120°-140° C.

Aromatic Amido-Oxy-Compounds.

O. Imray (Eng. Pat. 18,081, of 1915) describes interesting results obtained in the preparation of amido-oxy-compounds by electrolysis. In the electrolytic reduction of nitro compounds effected by a carbon cathode and by an anode of nickel, platinum, etc., more amine results as the cathode dissolves and is redeposited in a form to produce amine. Two metals in the cathode reduce action, such as Pb or Bi in the cathode itself, or a Pb cathode and Bi powder or salt added to electrolyte. Nitrobenzene, in presence of sulfuric acid, with such a cathode gives 50 per cent. p-amido-phenol (pure), and as a by-product 20 per cent. of aniline.

Amino-anthraquinone.

The Farbenfabrik vorm. F. Bayer und Co. (Ger. Pat. 295,624, of 1912) describes methods of manufacturing 2-amino-anthraquinone and various derivatives of the same. The starting point is 2-chloro-anthraquinone, or any of its derivatives which do not contain a strongly negative substituent, such as carboxyl, halogen, nitro or sulfo groups, in ortho position to the chlorine atom. The chlorine is replaced by NH_2, as the result of heating with aqueous ammonia under pressure, either with or without the aid of copper or copper salts.

An Improved Method of Separating Sulfonic Acids.

Prof. L. M. Dennis, of Cornell University, has perfected a method (Amer. Pat. 1,229,593, of June 12, 1917) for the separation of the sulfonic acids of aromatic hydrocarbons from the residual, dilute sulfuric acid at the end of the reaction. The mixture of acids is agitated thoroughly with benzene, in which the sulfonic acid is completely soluble. The resultant solution forms a supernatant layer, which is drawn off. From this solution the sulfonic acid is readily extracted by treatment with water. Hydroxides or carbonates of the various metals may be added to the aqueous solution thus obtained. and any desired salt can thus be prepared. (Prof. Dennis' recently invented method of manufacturing sulfonic acids was described fully in this journal for June, 1917, page 129.)

ARTIFICIAL COLORS

The Evolution of Coal-Tar Colors

[The editor of the English periodical, "The Dyer and Calico Printer," recently contributed to the London "Times" the following interesting historical outline of the successive features in the growth of the coal-tar color industry. It is so generally deemed to be almost entirely the product of German scientific and technical ability, that it is desirable to have brought out in bold relief the solid achievements of British and French chemists and dyers, in furthering its evolution.—Ed.]

In 1825 Faraday discovered benzene, the initial product for the production of aniline. William Henry Perkin, son of a London builder, left school in 1851 at the age of 15, and became a student under Professor A. W. Hofmann at the Royal College of Chemistry, London. Taking a keen interest in laboratory work and developing a great capacity for it, young Perkin became Hofmann's private assistant at the age of 17.

In his holiday time, in a small laboratory in his father's house, and entirely on his own initiative, he attempted the synthesis of quinine. He started with a derivative of toluidine as raw material, and as oxygen is absent in this substance and present in quinine he tried the effects of oxidation. The result was a brownish precipitate, which he showed Hofmann, who advised him to throw it away. Research chemists at this time had a strong objection to substances that would not crystallize or that were colored, and this combined these objections.

The Discovery of Mauve.

Perkin, however, continued his experiments and turned his attention to the oxidation products of aniline, so closely allied to toluidine. The result was the production of a mauve dye mixed with a much larger proportion of a black pigment. This was the famous pioneer dye mauveine, or Perkin's mauve, together with insoluble aniline black. The aniline he used was not pure; it contained toluidine. To accentuate the accidental nature of the discovery it has frequently been stated that if Perkin had not been working on impure aniline he would not have discovered the dye. This is not correct. Later he produced from pure aniline a mauve, which he called pseudo-mauveine.

The young inventor at once realized that he had produced a potential textile coloring matter of great beauty, and commenced a series of dyeing experiments. He found that it dyed silk without a mordant, but that cotton required preparation with tannin and tartar emetic. It was a basic dye, the most brilliant but least fast class of dyestuffs. Perkin next consulted Messrs. Pullar, the Perth dyers, who gave so favorable an opinion that he at once took out a patent. This was in 1856.

Greenford Green Works.

In partnership with his brother, Thomas Dix Perkin, and his father, who put most of his capital into the venture, the works at Greenford Green, near Harrow Hill, were started on a modest scale in the following year under the style of Perkin and Sons. The mauve dye was quickly in vogue with the silk dyers. British cotton dyers and calico printers objected to the high price and complained that it would not stand bleaching powder. The French textile printers took it up more readily, and when their patterns appeared in the markets all other printers had necessarily to follow suit. Mauveine was supplanted in the course of time by faster violet dyes, and its last employment in England was for the coloring of postage stamps.

With W. H. Perkin busily engaged on research and his brother energetically and capably conducting the sales department, the business prospered. Other dyes were put on the market, notably synthetic alizarin. Colin and Robiquet, Frenchmen, had in 1826 isolated the coloring principle of madder and called it alizarin, from the Levantine name of the plant, alizari. Graebe and Liebermann, Germans, first synthesized this substance by fusing dibromoanthraquinone with caustic potash, far too expensive a process to be employed commercially. The practical solution of the problem was found in substituting anthraquinone sulfonic acids for the bromine compound. Perkin, Caro, Graebe and Liebermann were all working at the same time on these lines. Perkin's work was entirely independent. On May 20, 1869, he sent samples, dyed with artificial alizarin, made with sulfonic acid, to Mr. Robert Hogg, of Glasgow. Unfortunately, he did not at once take out a patent. Graebe and Liebermann's specification is dated June 25 of the same year; that of Perkin one day later. As regards the actual manufacture, the Greenford Green works in 1870 were the sole source of supply of the artificial alizarin. Perkin eventually sold his patent rights to Brooke, Simpson and Spiller, who resold them to Burt, Bolton and Hayward. These firms were in successive occupation of the works at Greenford Green. On the expiration of the patents they passed into the hands of the British Alizarin Company, still a flourishing concern.

Perkin, it must be noted, was the first to prepare an artificial perfume from coal tar. This was coumarin, the odoriferous principle of the Tonka bean. In the researches that led to this result he discovered reactions, which have since been of essential service in the synthesis of indigo.

Other British Dye Makers.

Perkin's initiative quickly led to the evolution of a British coal-tar color industry. Before 1860 Simpson, Maule & Nicholson and Roberts, Dale & Co. were at work and prospering. By 1865 they were joined by Read Holliday & Sons, Dan Dawson, Williams, Thomas & Dower and Levinsteins. By far the greatest development took place in Germany, not from any scientific or technical superiority, but by reason of economic advantages. The founders of the German industry were not chemists, but sound men of business, with an imagination which displayed to them the possibilities of the future of the synthetic colors, and an admirable foresight which led them to reserve their profits and invest them in the business. Bismarck had not yet converted the King of Prussia into the German Emperor, and Germany was a collection of separate states. The result was that German patent law was in a state of hopeless confusion and the German manufacturers exploited British patents with impunity. British patents could not be patented in Germany with any sort of a guarantee of security and the manufacturers of the Fatherland used any English working process that they could discover, without paying anything in the shape of a royalty. Our pioneer, then Dr. Perkin, F.R.S., remarked to the writer in this connection: "We could not protect our own patents in England, much less abroad."

As an example of the clear insight of the future which was a great factor in the essential German success, take the case of alizarin. In 1870 a combine of German manufacturers of alizarin was formed, and for some years netted a clear million sterling annually from this dyestuff alone. A large portion of this huge profit was wisely devoted to building and equipping modern factories, and to the endowment of perfectly-equipped research laboratories, occupied by ample staffs of specially trained chemists. Success in research is on the side of the heavy battalions. In proportion to the number of chemists engaged, probably more important discoveries in the field of dye making have been made in England and France than in Germany.

Aniline Black.

The Rhine factories have had the lion's share of the profits from aniline oil and aniline hydrochloride, and yet the long history of the evolution of aniline black is remarkable for the absence of German names. The step-by-step progress of the art is almost entirely due to England and France. It is true that Germany can claim old-time laboratory experiments on aniline, obtained from the dry distillation of indigo, but these academic researches had been completely forgotten when Perkin obtained aniline black in powder, in commercial quantities, as a by-product of his mauve. This insoluble black was used by the calico printers as a pigment color. Crace Calvert first produced the black on the fibre and showed calico prints of it at the Exhibition of 1862. Lightfoot, an Acrington calico printer, prefected the process to such a degree, that he may be considered the veritable inventor. Lauth, a Frenchman, realized the most important improvement of Lightfoot's black. This was in 1864, and his process is still in current use. So far these were printing processes. Boboeuf, a Frenchman, took out the first patent for dyeing hanks, and his process is still largely used in the north of France. Prud'homme, a Frenchman, completely solved the problem of producing white and colored effects on aniline black. Professor A. G. Green, as lately as 1907, made the highly important discovery that the oxidation of aniline can be effected by the oxygen of the air, thus avoiding tendering.

On the mechanical side Thom, a Lancashire man, produced the first practical apparatus for steaming the dyed or printed goods, and a Salford firm improved this to such an extent, that the machine is known universally, in technical literature as the Mather and Platt.

These are the most important steps in the evolution of this black. Even in minor matters the progress of the art has been due mainly to England and France.

Retirement of W. H. Perkin.

In 1873, at the early age of 37, W. H. Perkin decided to retire from business. His father was dead, and he and his brother had realized fortunes. The reasons for the step were many. Greenford Green, in many ways, was unsuitable for dye-making. In any case, to keep abreast of competitors, the necessity of doubling or trebling the factory was realized, and the Perkins were satisfied with the profits they had accumulated and unwilling to risk them in the extension of a business which was beginning to be heavily handicapped in England. They were weary of litigation. Possibly a main reason of the decision was that Mr. W. H. Perkin's mind was turning to research in other directions, unconnected with commercial activities. He turned his house at Sudbury into a series of well-equipped private laboratories, building for himself a larger dwelling house close at hand. It will be within the remembrance of many, that as Dr. Perkin, F.R.S., he lived to celebrate the jubilee of his discovery. The scientific world joined in the celebration, and in the same year—1906—he was knighted. He died the following year.

Rapid Development of the Industry.

The coal-tar color makers have aimed at simple application in textile coloring on every description of fibre, combined with qualities of fastness suitable for every possible requirement. Direct cotton colors have been introduced capable of dyeing that most inert of textiles, cellulose, in a simple salt bath, without previous mordanting of the fibre. The sulfur colors, with the exception that they require dissolving in, or reducing with, sodium sulfide, are as simple in application and have an excellent fastness to washing and light. The first of the modern vat dyes, apart from artificial indigo, was introduced in the year of the Perkin Jubilee. This thio-indigo red approaches in its composition indigo on the one hand, and the sulfur dyes on the other; and can be reduced in the vat after the manner of indigo dyeing, or like the sulfur colors with sodium sulfide. Primuline, the discovery of A. G. Green, was the first of a highly important group of dyestuffs which can be diazotized and developed upon the fibre. For instance, primuline, developed with b-naphthol, gives a red, with resorcinol an orange, and with phenol a yellow. Dyes used in a simple bath of acid were introduced for wool, and another class, giving a high resistance to milling are dyed on chrome-mordanted wool, or together with the chrome in a single bath, or are dyed and then after-chromed. Sodium di-chromate was not used in the dyeing trades before the advent of the coal-tar colors. It is now used in enormous quantities. The vat colors, used for both wool and cotton, are the most modern of dyes. On cotton they realize the ideal of fastness, resisting constant visits to the laundry, and outlasting the material itself. This is necessarily a mere glance at the types of dyestuffs which have been introduced for every special purpose.

If the textile colorist's work has been simplified in some directions, it has been rendered more difficult in others. He has the choice of a multiplicity of dyes, and the wisdom of his choice may determine the difference between profit and loss. Whereas his ante-coal-tar color brethren kept more or less to long-traveled paths, the modern dyer and printer is working under constantly changing conditions. Indigo, madder, and logwood were the coloring matters used on a wholesale scale before the days of Perkin, and each was in the hands of specialists of life-time experience. Now the color makers are not only in competition with each other, but with themselves, so to speak. No sooner do they put a color onto the market than they try to improve on it, and a much used dyestuff may be almost obsolete in a decade.

The introduction of the coal-tar colors has had important results on the natural dyes. Logwood was formerly sent to the dyer in logs and chips, and the "ageing" process, that is, the oxidation of the coloring principle, was a delicate operation which required experience. This, and other woods, are now sent out in powder and in liquid extracts, ready for the immediate use in the dye bath. Cutch, fustic, Persian berries, and other largely used natural colors are also prepared in the same way. The introduction of the synthetic dyes led gradually to a very extended use of machinery. As a rule, this is of a simple description; but it has, of course, almost revolutionized dye-house practice, and has led to a remarkable speeding up of the work.

The Physical Basis of Color Technology.

In the Journal of the Franklin Institute for July, 1917, M. Luckiesh, of the Nela Research Laboratory, contributes an exhaustive study on "The Physical Basis of Color Technology," which contains much of interest to those engaged in the analysis of coal-tar colors. The details of procedure for the use of spectro-photometric methods in the study of pigments and of soluble dyes are given in great fulness. These methods furnish data which promise to be of manifest utility in the selection of soluble coloring materials for a variety of purposes.

Government Control of the British Dyestuff Industry

The president of the British Board of Trade has established a special department of the Board for the temporary control of the dye industry, particularly in regard to expansion and the details of manufacture. The object of the department is the further development of the industry in Great Britain. The executive oversight is vested in Sir Evan Jones with the official title of Controller of Dyes.

The appointment of a controller, who is not a professional chemist, has excited much adverse criticism. One of the most forcible expressions in this connection comes from Prof. H. E. Armstrong, who did so much in 1915 to formulate the necessity of unity and government co-operation in building up the British dyestuff industry.

There is so much in common between the American and British efforts to create self-contained national dyestuff industries, that a portion of Prof. Armstrong's comments on the action of the Board of Trade may profitably be reproduced.

"A year ago I drew special attention to the critical condition of the dyestuff industry, owing to our failure to bring about a satisfactory and comprehensive organization of the very numerous interests which must be brought into effective co-operation if our needs are to be supplied and the industry is to be maintained in competition with other countries.

"To quote the opening paragraph of my article on the subject:—

"'It is beyond question that the situation in which this British dyestuff and allied industries are placed at the moment is extremely serious, and that the steps taken thus far have been such as to jeopardize the future rather than to establish conditions which would have promoted development. The failure of the Government to deal with the problem comprehensively, especially the action which they have taken in subsidizing only one of the firms in the country, more or less to the detriment of the others, is producing results which must militate against progress, and may even render the ultimate recovery of our position impossible.'

"It is well known that very little use has been made in the interval of the scientific talent of the country. There has been much boasting of what has been done by 'research'; but it amounts to very little in comparison with what has to be done. Individual firms may have made substantial progress as well as money, but this appears to have retarded rather than promoted collective development, as the terms on which these firms will now enter into association have been advanced. Organization, easy a year ago, is more difficult today.

"There has been an expectation of late that a comprehensive organization of the dyestuff industry was about to be effected, but apparently the negotiations have failed. Instead, we were told on June 19 that Sir Evan Jones, Bt., M.I.C.E., had been appointed Commissioner for Dyes and head of a special temporary department of the Board of Trade to promote the further development of the dye-making industry in the United Kingdom. The department has been formed to deal with matters relating to the encouragement, organization, and, so far as necessary, the regulation of the dye-making industry. In addition, we are now informed that Sir Evan Jones has also been appointed Controller of a Petrol Control Department—as if dyes were not sufficient for one man.

"Verily we are given stones where we ask for bread. What the country needs is a self-respecting, self-contained, self-governing industry—not a new bureaucratic Government Department to red-tape and delay progress. Sir Evan Jones is distinguished as an engineering contractor—no one will question his ability in his own sphere. But how can an engineer have the technical feeling required in an industry of so special and complex a character as that of dye-making? There are few professed chemists who have mastered it, who can deal with its problems intelligently. As well ask a chemist to superintend the manufacture of ordnance or the building of ironclads!

"It cannot be too clearly and forcibly stated that there can be no real progress in our country in matters in which special technical knowledge is of primary importance so long as control is placed in the hands of men without such knowledge. During the war various individuals and innumerable committees have been appointed to deal with scientific problems of which they have no real understanding, and vast sums have been squandered. The worst case of all, perhaps, is the appointment of purely literary men, without scientific training or experience, to superintend and organize the work of scientific and technical research. It is things such as these that make one despair of our future when once more competition rules the world."

A New Class of Yellow Azo Colors.

Meister Lucius and Brüning (Hoechst) obtain a new series of yellow, chromable azo colors (Ger. Pat. 295,051) from the action of 1-sulfo-aryl-pyrazolons, or their derivatives on diazo compounds of anthranilic acid and various substitution products of the same.

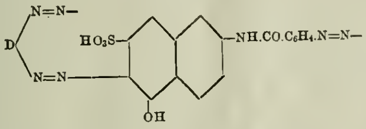
A New Series of Sulfur Yellows.

The Bayer Co. (Ger. Pat. 295,104) gives details regarding the production of very fast yellow sulfur dyes by the use of alkaline polysulfides on the carboxylic acids and the sulfonic acids of the ethylated amines of benzene, naphthalene and other aromatic hydrocarbons.

New Azo Colors for Use on Vegetable Fibers

Herbert Levinstein and James Baddiley, of Blackley, Manchester, England, assignors to Levinstein, Limited, of Manchester, have brought out (American patent 1,232,056, of July 3, 1917) a new series of substantive azo colors, intended for use chiefly on cottons and other vegetable fibers.

This new series is essentially an elaboration of a class of colors described by the inventors in 1912 (Br. Pat. No. 27,525 of 1912) and obtained by coupling two molecules of resorcin with a tetrazo body of the following general formula:—

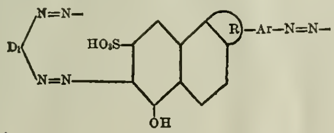


In the above formula D is a residue of the general constitution

Ar.CO.NH.Ar

Ar representing an aryl radical. Bright substantive orange, red, or brown dyestuffs are obtained by this reaction, which, after dyeing, are fixed with formaldehyde on vegetable fibers. Shades faster to boiling soap solutions than those produced by developed dyestuffs are thus secured far more conveniently than by methods involving the use of either developed or vat colors.

In their latest patent the inventors enlarge notably the range of shades by coupling two molecules of resorcin with tetrazo compounds of the formula:—



R indicates a ring formation containing nitrogen and includes 1.2-aminoaryl: triazol-, oxazol-, thiazol-, imidazol-, azimido-, residues of the compounds indicated in the formula.

D_1 may be a residue of the following constitution

—Ar. CO.NH.Ar—

—Ar—Ar—

—Ar—CH=CH—AR—

—Ar—N=N—Ar.

$-Ar-\underset{\diagdown O \diagup}{N-N}-Ar$

—Ar—S—Ar—

—Ar—O—Ar—

—Ar—CS—Ar

—Ar—O—CH_2—CH_2—O—Ar

—Ar—O—C_6H_4—O—Ar—

Ar indicates an aromatic radical.

The general method is illustrated by the following example:

256 parts of m-m-diamino-azoxy-toluene are converted into the tetrazo compound by means of 138 parts of sodium nitrite, and the necessary amount of hydrochloric acid. The tetrazo compound is combined in soda-alkaline solution with 356 parts of m-amino-phenyl-1 : 2-naphthimidazol-, 5 oxy-, 7-sulfonic acid. The intermediate compound thus obtained is rediazotized by means of 68 parts of sodium nitrite and the necessary quantity of hydrochloric acid. The resulting tetrazo compound is combined with 220 parts of resorcin in the presence of an excess of sodium carbonate. When the combination is completed the dyestuff is isolated in the usual manner. It dyes cotton directly. When the dyeings are aftertreated with 3% formaldehyde (40%), at a temperature of 70°—80° C., for 20—30 minutes, yellowish-red shades, extremely fast to boiling soap solution are obtained.

If instead of diamino-azoxy-toluene in the above example, m-amino-benzoyl-m-phenylene-diamine is used, similarly fast shades are obtained, but of a yellowish tone.

Color Lakes Derived from Complex Tungstic Acids

Carl Immerheiser, of Ludwigshafen-on-the-Rhine, and Anton Beyer of Mannheim, Germany, assignors to the Badische Anilin & Soda-Fabrik, of Ludwigshafen, describe (Amer. Pat. 1,232,552, of July 10, 1917) the preparation of a class of color lakes possessing great brilliancy, and extremely fast to water and light, obtained by precipitating basic coal-tar coloring matters by means of a complex acid containing tungsten, for instance, phosphotungstic acid and silcotungstic acid. Especially satisfactory results are secured by using the phospho-duodeci-tungstic acid and the phospho-luteo-tungstic acid described in the Zeitschrift für Anorganische Chemie, vol. 1, page 431.

The following example serves to illustrate the process employed in making the different lakes: Mix one hundred parts of a ten per cent. paste containing aluminum hydrate and barium sulfate (obtainable by mixing together aqueous solutions of ten parts of aluminum sulfate containing 18% Al_2O_3, five parts of calcined sodium carbonate and twelve parts of barium chloride) with a solution of one part of Crystal Violet (a salt of hexa-methyl-triamino-tripheny-carbinol) in one hundred parts of water. Then add an aqueous solution of from two to three parts of acid sodium phospho-duodeci-tungstate until the coloring matter is completely precipitated. The pure violet lake is filtered off and can be worked up in the usual manner.

The precipitation can take place at ordinary or elevated temperatures, and with or without the addition of Turkey red oil, sodium acetate, or other similar substances. The precipitation can, for instance, be carried out in the presence of any suitable substratum, and the concentration of the various ingredients can be varied within wide limits.

Instead of Crystal Violet other basic coal-tar coloring matters can be used, such as other violets of cognate nature, the dyestuffs of the Rhodamine, Auramine, and Malachite Green series, or the dyestuff which can be obtained by condensing benzaldehyde-o-sulfonic acid with diethyl-aniline and sulfonating the condensation product and dyestuffs of a similar nature. In lieu of the sodium phosphoduodeci-tungstate other complex acids of tungsten, or salts thereof, are equally suitable for the purpose in view.

New Wool Disazo Dyestuffs

Eugen Anderwert and Heinrich Schobel, of Basel, Switzerland, assignors to the Society of Chemical Industry, of Basel, announce (Amer. Pat. 1,233,742, of July 17, 1917) the discovery of a new series of disazo colors, applicable to wool and other animal fibers, giving very pure tints of marked fastness to both light and washing.

The members of the new series are obtained by combining the tetrazo derivative of a 3-3′-diamino-diaryl-methane compound with two molecules of azo dyestuff components, whereof at least one is a molecule of a naphthol-sulfonic acid. As 3-3′-diamino-diaryl-methane compound may be employed advantageously the 3-3′-diamino-4-4′-dimethyl-diphenylmethane, the 3-3′-diamino-diphenylmethane and their derivatives.

The resultant dyestuffs yield a variety of tints ranging from scarlet to orange and yellow.

The reaction may be varied in numberless ways. The following examples illustrate some of the more important products and the methods of their preparation:—

Example 1: 22.6 kg. of 3-3′-diamino-4-4′-dimethyl-diphenyl-methane are dissolved in 60 kg. hydrochloric acid and tetrazotized at about 0° C. with a solution of 14.2 kg. sodium nitrite. The resulting solution of tetrazo compound is poured, under constant stirring, into a solution of 52 kg. 1-4 naphthol-sulfonic acid and of 50 kg. sodium carbonate. After standing for a long time, the mass is heated at 60° C., and the dyestuffs is salted out, filtered off, pressed and dried. It constitutes a red powder, which dissolves in water and in concentrated sulfuric acid with a red coloration. It dyes wool in an acid bath very pure red tints possessing a very good fastness to washing and to light.

Example 2: By substituting in Example 1 for 1-4-naphthol-sulfonic acid the same quantity of 2 6-naphthol-sulfonic acid, the resulting dyestuff dissolves in water and concentrated sulfuric acid to a yellow-red solution. It dyes wool in an acid bath very pure yellow-red tints of a good fastness to washing and to light.

Example 3: The tetrazo compound, prepared according to Example 1, is poured, while stirring, into a solution of 34.8 kg. 2-naphthol-3-6-disulfonic acid and of 50 kg. of sodium acetate, at about 0° C. After stirring for about 2 hours the intermediate product is obtained. It is poured into a solution of 15 kg. of b-naphthol, 13 kg. of soda lye of 30 per cent. and 50 kg. of sodium carbonate. After stirring for a long time, combination is completed and the dyestuff is isolated in the usual manner. It dissolves in water and concentrated sulfuric acid to red solutions and dyes wool, in an acid bath, pure scarlet-red tints, of a good fastness to fulling and to light.

Example 4: The solution of tetrazo compound derived from 22.6 kg. of 3-3′-diamino-4-4′-dimethyl-diphenyl-methane, according to Example 1, is mixed with the solution of 27.6 kg. of 1 (4′-sulfo-)-phenyl-3-methyl-5-pyrazolone and of 50 kg. of crystallized sodium acetate. After formation of the intermediate product, requiring about 2 hours, the mass is poured into a solution of 26 kg. of 1-4-naphthol-sulfonic acid and 50 kg. of sodium carbonate. The combination being effected, the dyestuff is isolated in the usual manner. It dissolves in water and concentrated sulfuric acid to orange solutions and dyes wool, in an acid bath, red-orange tints fast to washing and to light.

Instead of the 1-(4′-sulfo-)phenyl-3-methyl-5-pyrazolone can be employed with similar success the 1-phenyl-3-methyl-5-pyrazolone itself, or its nitro- or carboxyl derivatives, the acetoacetanilide, the methyl-ketol, etc.

Example 5: 19.8 kg. of 3-3′-diamino-diphenyl-methane are tetrazotized with 60 kg. of concentrated hydrochloric acid and 14.2 kg. of sodium nitrite. The resulting tetrazo compound is poured while stirring into a solution of 52 kg. of 1-4-naphthol-sulfonic acid and of 50 kg. of sodium carbonate. After some hours, the dyestuff is separated by heating to 30° C. It is salted out, filtered off, pressed and dried. It constitutes a red powder dissolving in water and concentrated sulfuric acid to red solutions. It dyes wool, in an acid bath, pure scarlet-red tints of a good fastness to fulling and to light.

Example 6: By substituting for the 1-4-naphthol-sulfonic acid employed in Example 5 the same quantity of 2-6-naphthol-sulfonic acid, the resulting dyestuff dyes wool in an acid bath pure yellow-red tints of good fastness.

The inventors attach the most importance to the bright red dye obtained in the first example. The general reaction is, however, one of distinct promise.

The Use of Phosphomolybdic Acid in Producing Color Lakes.

Carl Immerheiser, of Ludwigshafen-on-the-Rhine, Germany, assignor to the Badische Anilin & Soda-Fabrik, of Ludwigshafen, has recently devised

(Amer. Pat. 1,232,551, of July 10, 1917) a method for preparing an extensive series of color lakes which consist of insoluble combinations of various basic coal-tar dyes with phosphomolybdic acid. These lakes possess great brilliancy, are extremely fast to water and very fast against the action of light.

The following example serves to illustrate the general method of preparing such a lake: Mix together 10 parts of heavy spar, a solution of 5 parts of aluminum sulfate (containing 18% Al_2O_3) in 50 parts of water, a solution of 2½ parts of calcined soda in 25 parts of water and a solution of 6 parts of barium chloride in 60 parts of water. Then add a solution of one part of Diamond Green G (a salt of tetra-methyl-diamino-triphenyl-carbinol) in 200 parts of water, and a solution of from 2 to 3 parts of sodium phosphomolybdate in from 20 to 30 parts of water. Filter off the color lake and prepare it in the usual manner.

Use of Methyl Red as an Indicator in the Determination of the Hardness of Natural Waters, S. A. Kay and Susan H. Newlands (J. S. C. I., 1916, *35*, 445), describe modified procedures for the determination of temporary and permanent hardness by the use of Methyl Red. It is claimed that the proposed methods are more accurate than those now in common use.

NATURAL DYES

The Art of Dyeing

A Survey of Processes and Methods

By Clement Bolton

[The following clear and compact portrayal of the current methods employed in the use of coloring materials is from the pen of a leading British authority, and will be welcomed by those conversant rather with the manufacture and sale of dyestuffs.—Ed.]

The affairs of the dyeing trade have had much publicity given to them during the past two and a half years. It is possible, however, that the somewhat sensational treatment devoted to the subject has left but a hazy idea of the trade as a whole. A general survey may therefore be useful in helping to put matters into better proportion.

Dyeing processes are applied to many materials. The most important are the textiles. It is difficult to supply a short definition of all that is implied in the word dyeing, but in general it means the giving to some material a color that is more or less uniform, thorough, and permanent. This differentiates it from painting and printing.

In "painting" the pigment or coloring matter is superficial and obvious. The object painted is covered and hidden by the paint. "Printing" connotes some idea of pattern, and is usually, but not always, superficial. "Dyeing" suggests dipping, or at any rate a very thorough impregnation. Color is not tangible matter, but only an attribute. Dyed material must not give tangible evidence of the coloring matter, but only of the attribute. The dyer takes, say, some wool and some substance with the attribute of redness. At the finish of his operations the wool has the redness, but what of the colored substance from which the redness came? It has gone to practically oblivion—that is, if the wool has been properly dyed. If that colored substance is actually visible on the surface of the wool then it is not dyed, but only daubed on. If the wool satisfies the eye, yet if mere rubbing on white paper or a white handkerchief causes a stain, then the advance from daubing to proper dyeing has not been completely achieved.

The Question of Fastness.

There are many agencies which tend either to destroy the color of a dyed fabric or to dissociate the union of dye and fibre: for example, washing, rubbing, and light. No dyeing attains absolute permanence against every adverse agency. Still some colors are as permanent as the material on which they are dyed. This is surely as much as is necessary to expect. All-round fastness is really more than is necessary in many cases. For instance, if upholstering or carpets, or bookbinder's cloth are fast to light and rubbing, what does it matter if they are not fast to washing—they are never washed? Underclothing should be fast to washing and rubbing and perspiration, but need not be particularly fast to light. Thus, if the dyer meets the reasonable requirements of the material he has attained to a reasonable degree of perfection.

We said that dyeing connotes the idea of dipping, but this must not be taken to mean that it is sufficient to immerse in any colored solution to get a corresponding color on the article dipped. The dyer's lot is not so easy. For instance, copper sulphate is known as blue stone because of its color, but it gives to wool a light greenish drab tint, and affects cotton not at all. A solution made from ammonia and copper oxide has a still more intense blue, but boil any textile material in it and the puzzle will be to recover it, for instead of being dyed it will be dissolved. In fact a cuprammonium solution of cotton is one source of artificial silk. The very concentrated solution is squeezed through capillary tubes into a precipitating reagent, and the cotton materializes again as rod-like, lustrous threads.

There are, of course, some coloring matters that will dye from simple solutions. One series of coal-tar colors is called the basic series. The well-known bright red, magenta is one of them. Most of the series will dye wool or silk direct from a hot solution. There is another series called the acid dyes. From simple solution they give wool or cotton only thin, washy shades. But let about as much sulfuric acid as dye be present, and the wool will be well dyed. The cotton will be left white.

Direct Cotton Dyes.

Another series is that of the direct cotton colors. These will dye both cotton and wool to some extent from simple solution, but much better if the specific gravity of the bath is raised by the addition of salt. Still further improvement is obtained if, in the case of cotton, some alkali is added to the bath, or, for wool, some weak organic acid, for instance, acetic acid. It is obvious from this statement that these dyes are soluble in either weak acid or weak alkali. But the sulfur colors, another very important series produced by the reaction of sulfur or sodium sulfate on various coal-tar intermediates, require a rather caustic alkali for their solution. Cotton and linen can stand this alkali, and as the colors have excellent fastness, and are very cheap, they are used to an enormous extent on the vegetable fibres. But wool and silk are dissolved by quite weak caustic alkali, and the series is therefore practically useless for these fibres.

Dyeing is not always a matter of one dip. Until the advent of the coal-tar dyes it was the exception. It was one of the advantages of these dyes that they gave to many branches of the trade the possibility of managing with one bath. The average fastness of the one-dippers, however, is poor. Dyes that are put on most easily come off most easily as a rule.

As to the theory of dyeing there is great controversy. The one-dip processes we have mentioned lend support to the solution theory. The material to be dyed, though a solid, is considered to be a solvent. The water of the dye-bath is, of course, also a solvent and has the dye held in solution. The solution has mobility and distributes itself between the two solvents, the water and the fibre, until equilibrium is established. If the water is the more powerful solvent a good deal of dye will be left in it, but if the fibre has the greater power, then the liquor becomes exhausted of dye. The dyer adds assistants to his dye-bathes—sometimes they are meant to help exhaustion and sometimes to retard it. In the former case the idea is to get all the value possible out of the bath. In the latter case it is to prevent the color from rushing on and so producing uneven results.

Dyeing processes which require two or more stages seem to the present writer to require some chemical explanation. Instead of conveying colored substances into the pores of the fibres, the dyer actually produces the substance in situ. This is what happens with "mordant" dyestuffs. The characteristic of these is that they give colored precipitates when boiled with metallic salts known as mordants. These precipitates are called "lakes," and can be used by painters as pigments. The dyer, however, does not usually prepare the lake away from the fibre. He gets one constituent into the pores and then brings the other to it, and the lake is formed in the very substance of the material. It is easier to do this on wool than on cotton. Wool is more active, chemically speaking, than cotton. If it is boiled in solutions of salts of iron, copper, tin, alum, or bichromates, the salts are dissociated, the metal part being absorbed by the wool. A second treatment in boiling solution of dye results in lake formation and a fast dyeing. From the same dyestuff various colors can be obtained by using various "mordants," as the metallic salts are called. Thus alizarin with iron gives a violet, with chrome a maroon, with alum a scarlet, and with tin an orange. Such a dyestuff is called polygenetic.

Complicated Processes.

The cotton dyer has to go beyond two stages when fixing many mordant dyes. Cotton has no great affinity for either the mordant or the dye. He therefore requires some chemical which has a double affinity—on the one hand for the cotton, and on the other hand for the mordant. Tannic acid and its near relations provide this. The cotton is steeped either in tannic acid or some tannin material, such as extract of sumach, chestnut bark, or myrabolans. The tannic acid and its relatives are absorbed, though not very strongly. The next treatment, with some metallic salt—say, acetate of iron—has the twofold benefit of fixing both the tannic acid and the metal. Then the dyestuff can be put on top, and a color lake is fixed in the fibre. The chief mordant dyestuffs are logwood, for blacks on all fibres, and alizarin, for Turkey red on cotton. The latter furnishes, perhaps, the most elaborate of dyeing processes. The cotton is first treated with oil, then with tannin, then with mordant, in this case alum, and then with dye. Some of the treatments have to be repeated. The total number of operations is 14, and the time occupied may be several days. Even this is an improvement on the original Eastern procedure, which, it is said, lasted three months. The alum-alizarin lake on wool may be fixed in two hours.

The older mordant dyes had not much affinity for the textile fibres, hence the usual practice of mordanting first. But the gap between them and the acid colors is now filled in by others whose properties partake of both groups. They have proved particularly useful in wool dyeing. They are applied, first, from an acid bath, and then fastened with a mordant. Usually the mordant causes a considerable change of shade. A black dye, for instance, shows red at the first stage, and turns to black by treatment with a bichromate. The acid mordant blacks are superior to the old-fashioned logwood black in most respects. They were used in enormous quantities before the war, and will be used again as soon as they can be made.

The acid and direct cotton colors are mostly the product of certain coal-tar intermediates called amines, aniline itself being a typical example, combined with others called phenols and naphthols by means of what is known as a diazotizing process. It is only the soluble products that are dyes, but there are others, which, being insoluble, can be used as pigments. The dyers of vegetable fibres can effect the manufacture of these pigments in the pores of cotton, linen, etc.

Many Branches of Trade.

From the brief description it will be readily understood that the dyeing trade is not one, but many. The chief divisions are, according to the material—wool dyeing, cotton dyeing, etc. Each of these further subdivides according to the stage of manufacture. The material may be raw, spun into thread, or woven in the piece. The thread or yarn may be in several forms—hanks, warps (sometimes miles long), cops, or cheeses.

The tendencies in the dyeing trade are similar to those in other trades that cater for the public. Some people require the best, no matter at what cost. Others seek cheapness, with its necessary concomitants. With others, again, novelty, nice or otherwise, is the requirement. The dyeing trade caters for them all.

Better results, new effects, less costs, simpler processes—the dyer aims at all these. A recent writer has expressed it rather differently. He says that the perfect dyestuff, to which we are evolving, must dye level, cost nothing, and smell like violets. But the youngest of dyers will have matched off his last batch, and still the perfect dyestuff will be in the future.

Fire in the Works of the American Synthetic Color Co.

The American Synthetic Color Co., at Stamford, Conn., lost by fire on July 21 one of the buildings of its extensive plant, and a small annex. The mechanical equipment of the building was destroyed, and there was a serious loss of material in course of manufacture. This plant has been an active factor during the past two years in the production of coal-tar intermediates, and the company has formulated plans for taking up the manufacture of dyestuffs.

Lullaby.

Atomize antiseptics as baby girl sleeps,
While the infra-red ray through the nursery room sweeps.
Let powdered iodoform fall in soft flakes,
And kill all bacilli ere baby awakes. —*Life.*

Color Trade Journal, Vol. 1, No. 1, August, 1917

Published by the "Color Trade Journal, Inc.," 200 Fifth Avenue, New York, J. Merritt Matthews, Pres.; C. Cyril Bennett, Sec.-Treas. $5 Per Annum.

It is a pleasure to welcome to the group of periodicals devoted to the furtherance of American chemical industry this latest addition, the *Color Trade Journal*. The initial number gives every promise that it will do stalwart work in furthering, stimulating and protecting the many diversified interests in this land which are engaged in the production of coloring matters and in their application.

Dr. J. Merritt Matthews, the editor, has been closely identified for many years with the struggle to build up an American dyestuff industry and with every phase of the utilization of colors in the textile and allied branches. No one is more familiar with the difficulties to be overcome in making our American color industry self-contained and independent; no one is better fitted to impart helpful counsels and indicate the most needed and the most favorable lines of progress. As the author of a standard manual for laboratory instruction in dyeing, he has earned the grateful regard of all the younger school of tinctorial chemists in this country.

Associated with Dr. Matthews is Mr. Cyril Bennett, well known, especially in Washington, as a journalist of forceful style, closely familiar with economic problems, and personally identified with the movement to ensure by suitable legislation the permanence of our young dyestuff industry.

The first number contains a variety of articles contributed by men of prominence in color chemistry and closely related fields. There is an abundance of illustrations, including tasteful vignettes of most of the contributors. Paper and typography are excellent. The handsomely executed cover design in colors is most happily in harmony with the character and purpose of of the journal.

All in all, the *Color Trade Journal* is a credit to American trade journalism, and our color chemists have every reason to appreciate Dr. Matthews' admirable work on their behalf. Its appearance is an added proof of the conviction by all connected with the dyestuff industry in our country, that it is founded upon a sure and permanent basis, ready to face the struggles for supremacy on the part of foreign rivals, which may follow the end of the great war.

New Quarters for National Aniline & Chemical Co.

The National Aniline & Chemical Co. will shortly occupy three floors of the new Heckscher Building, at 244 Madison Avenue, New York City. For over twenty years the company has been located at 100 William Street.

Disastrous Conflagration in the Factory of the Seydel Manufacturing Co.

On July 9 there was a serious fire in the dyestuff works of the Seydel Manufacturing Co., Jersey City, which caused a loss of about $150,000. The disaster resulted from the boiling over of a large tank containing benzoic acid. The contents took fire and the flames spread rapidly throughout the large building. A huge pall of dense, black smoke hung over the entire neighborhood, extending for half a mile in every direction. The evolution of noxious fumes was such that firemen were seriously hindered in their efforts to check the flames. Nine firemen were rendered unconscious for varying periods. There were, fortunately, no fatalities. Railroad traffic on the adjacent railway lines was interrupted for over two hours.

Explosion in the Beckers Works.

An explosion occurred on July 1 in one of the buildings of the W. Beckers Aniline and Chemical Works, in Brooklyn. Four operatives were seriously burned, one of whom is not expected to recover. The explosion was regarded as due to the presence of a large amount of easily combustible dust in the air, and there was no indication that it was brought about intentionally by outside parties.

Explosion in the Works of the Midvale Co.

There was a bad explosion of aniline oil and benzene in the plant of the Midvale Chemical Co. at Elizabeth, N. J., on July 7, causing damages to the extent of $50,000. The explosion was caused by a leak in an aniline still.

ULTRA VIOLET LIGHT

Its Application in Chemical Arts

By Carleton Ellis and A. A. Wells.[*]

This Is the Sixth Installment of an Article Dealing with Investigations Conducted by the Writers Into the Possible Application of Ultra Violet Light. The Present Installment Continues a Discussion of the Effectiveness of Its Rays for the Sterilization of Liquids as Compared to Ozone. Various Forms of Apparatus Are Also Described. Part VII Will Appear in the Next Issue.

PART VI

STERILIZATION OF LIQUIDS.

Ultra Violet Rays vs. Ozone.

Erlwein (J. Gasbeleucht, 1911, 54, 955; J.S.C.I. 1911, 1228) has made comparative experiments on the efficiency of many forms of lamps for producing ultra violet rays for sterilizing water, and states that none were found to be satisfactory; nor did the admission of air with the water lead to the formation of ozone or increase the sterilizing effect. The least consumption of energy was found to be given by a sterilizer in which the quartz mercury lamp was suspended in the axis of a swinging cylinder through which the water passed with a tangential motion. When this method was compared with the ozonization process, it was found that, to produce the same bactericidal effect on the whole of the water supply of Marseilles, the use of ultra violet rays would require an installation of 540 kilowatts and the ozone method an installation of 100—109 kilowatts. A drawing is given of a particular form of ozonizing apparatus made for domestic sterilization purposes in which the energy consumed varies from 10 to 60 watt hours according to the concentration of ozone required. The ozone method has the further advantage that a simple chemical test with iodide and starch applied to the treated water will show at once the efficiency of the process, instead of having to wait for some days for the result of a bacteriological cultivation test.

Production of Ozone.

A sterilizing apparatus used by *Jaubert* (French patent 415,574, July 19, 1909) consists of a horizontal quartz mercury vapor lamp surrounded by a jacket. The liquid to be sterilized is caused to circulate through the space between the lamp and the jacket. The liquid should contain air or oxygen in solution or suspension, so that ozone is formed when the liquid is subjected to the action of the ultra violet rays emitted by the lamp.

Use of the Photometer.

In the process of *Doulhet* (French patent 458,167, April 28, 1913) the lamp is placed in the center of the liquid to be sterilized and may be surrounded by a quartz jacket in order that it may be operated at a high temperature. If the lamp is placed directly in the liquid, metal supports are provided at the ends so that the electrodes are not cooled. A photometer, depending on the principle that ultra violet rays pass through quartz but not through ordinary glass, is used to ascertain whether the rays are traversing the liquid thoroughly. Baffle plates in the sterilizing chamber cause the liquid to flow in close contact with the lamp. The liquid, if opaque and containing fat globules, may be diluted with water before being passed through the apparatus, and concentrated subsequently under reduced pressure, or the sterilization may be carried out at such a temperature that the fat globules are melted.

Sterilizing Apparatus.

Von Recklinghausen (U. S. patent 1,156,947, October 19, 1915) describes an apparatus for sterilizing liquids, which consists of a tank divided throughout the greater portion of its length into two main compartments. One compartment is relatively shallow and near the top of the tank. In flowing from one compartment to the other the liquid passes over wiers or baffle walls in a thin stream and is exposed to the action of the light in thin films. The ultra violet light is located just above these baffle walls.

Walkley and Tubex Engineering Co., Ltd. (British patent 14,689, June 18, 1914) have devised an apparatus for the sterilization of liquids. The liquid is passed as a thin film over the inner surface of corrugated plates which are curved so as to form a cylindrical vessel inside of which the lamps emitting ultra violet rays are suspended. The plates may be curved in various shapes.

Apparatus for sterilizing water by means of ultra violet rays described by *Nogier* (French patent 420,281, Nov. 18, 1909; English patent No. 9,960, April 20, 1911; J.S.C.I. 1912, 356) includes a sterilizing vessel consisting of two chambers connected by a narrow orifice. This orifice is traversed by the horizontal tube of a mercury vapor lamp, so that the water, in passing from one chamber to the other, comes in close contact with the tube, which is made of quartz or other substance transparent to rays of short wave length. The flow of water through the sterilizing vessel is controlled by a device installed in the electric circuit. This device includes a cylinder provided with an inlet and an outlet for the passage of the water, and with a piston. A rod with a conical end projects downward from one side of the piston, and a pillar of soft iron projects upward from the other side of the piston. When the electric current is switched off, a spring, acting on the piston, presses the conical end of the piston rod into the funnel-shaped mouth of the inlet so that the flow of water to the sterilizing vessel is arrested. When the electric current is switched on, the piston is drawn upward by an electro magnet of soft iron situated directly above the pillar before mentioned, and the water then flows to the sterilizing vessel at a rate which is proportional to the intensity of the electric current.

---

[*] All rights of publication in book form reserved by the authors, Consulting Chemists and Chemical Engineers, 92-98 Greenwood Ave., Montclair, N. J.

In another apparatus proposed by Nogier (French patent 426,606, May 6, 1910) a circular tube is provided at intervals with partition plates or screens which alternately direct the current of water passing through the tube from the center to the periphery and vice versa. Quartz mercury lamps are situated in the tube between the partition plates and means are provided for introducing or removing the lamps without interfering with the flow of water.

In sterilizing liquids by means of ultra violet rays, *Linker* (U. S. patent 1,079,503, Nov. 25, 1915) recommends conveying the liquid to be sterilized through a central passage extending throughout the length of a mercury vapor lamp. One end of the tube is then turned backwards in the form of a spiral round the outer wall of the lamp. The tube is out of contact with the walls of the lamp and is sealed into each end of the passage so that a dead-air space is provided between the inner wall of the lamp and the tube.

In an apparatus for sterilizing liquids described by Kowalski (J.S.C.I., 1916, 379, British patent 1662, February 2, 1914) a guide wheel is placed across the passage through which the liquid flows and directs the liquid at an angle against the blades of another wheel, the axle of which is supported in the long axis of the passageway. The rotation of this turbine wheel gives an eddying motion to the liquid, which is then exposed to ultra violet light.

An apparatus of the Banque du Radium (French patent 426,277, April 29, 1910) consists of an arc lamp, or other lamp capable of emitting ultra violet rays, fitted at the top of a vessel into which the liquid to be sterilized is admitted. The supply pipe for the liquid is provided with a valve which is operated by an electro magnet in circuit with the lamp. When the lamp is working, the valve is opened and the liquid is admitted into the lower portion of the vessel through a central overflow pipe which contains a metal sieve. Should the electric current be interrupted, the valve is closed and its movement at the same time opens up communication between the vessel and a small drainage pipe so that the vessel is emptied and stagnant liquid does not collect when the lamp is not working.

In another apparatus of the Banque du Radium (British patent 15,010, June 27, 1911) the flat bottom of the apparatus is replaced by bottoms having the form of truncated cones, the angle at the summit of which is such as to enable the ultra violet rays to be more effectively utilized.

Use of Baffles.

Arrangements are described by Helbronner and von Recklinghausen (British patent 18,768, Aug. 9, 1910) for varying the rate of flow of a liquid in different parts of a conduit while the liquid is being subjected to the action of ultra violet rays. The portion of the liquid passing near the lamp may be caused to flow more rapidly than the more remote portions by placing suitable baffle plates in the conduit; these plates may have V-shaped pieces cut out of their upper edges or they may be perforated with holes of different sizes, the larger holes being at the top of the plates and the smaller ones at the bottom.

Special Forms of Lamps.

In another modification by Helbronner and von Recklinghausen (French patent 424,369, March 12, 1910) the lamp is movably suspended in a quartz chamber from which the air is exhausted, the liquid to be treated being directed against the sides of the chamber. The outlet pipe for the liquid is provided with a valve which is operated by the flow of the liquid and regulates the working of the lamp. The lamp may be removed vertically or horizontally from the lamp chamber. The liquid may also be passed through a tube containing an inner quartz tube in which is situated the lamp, or it may be circulated through a chamber containing a quartz tube in which an arc lamp is fitted. Means are also described for passing a current of water over the inner surface of the tube surrounding the mercury lamp. Lamps emitting ultra violet rays are also fitted inside quartz tubes extending from side to side of a closed chamber through which the liquid to be treated is passed.

Apparatus Using Rotating Cylinder.

Helbronner and von Recklinghausen (British patent 12,947, May 27, 1910) also propose to subject the liquid in the form of a thin layer on the surface of a rotating cylinder, to the action of rays emitted by a mercury vapor lamp which is situated close to a window in an outer casing which encloses the cylinder, or the lamp may be placed inside the cylinder if the latter be constructed of material which is permeable by ultra violet rays. In another form of the apparatus, the lamp is situated near an open end of the cylinder and reflecting surfaces are arranged so as to direct the rays to the periphery of the cylinder. An endless belt moving across the periphery of the cylinder or a syphon arrangement, may be employed for removing or periodically washing secondary products from the cylinder, the liquid being removed by a scraper and secondary roller, or by means of a jet of air.

Prevention of Leakage.

One form of apparatus proposed by Helbronner and von Recklinghausen (British patent 23,077, Oct. 5, 1910) has the lamp enclosed in a metal frame provided with quartz windows, the chamber thus formed around the lamp being supplied with air or other gas at a pressure slightly exceeding that outside the chamber when the latter is immersed in the liquid to be treated, thus preventing leakage of the liquid into the lamp chamber.

In another form of apparatus for sterilizing liquids von Recklinghausen (United States patent 1,204,721) proposes the use of an ultra violet lamp having the tube bent in the form of a U. The liquid to be sterilized is passed through a spiral column composed of quartz or similar material, the latter coil being in turn enclosed in another coil or in a water jacket in order to reduce the temperature of sterilization. Two or three modifications of this apparatus are shown. The advantage of an apparatus of this type is that equipment of comparatively small dimensions would be adequate for the efficient treatment of such amounts of water as might be used, for example, in households or offices for sterilizing water for drinking purposes.

Still another apparatus described by Helbronner and von Recklinghausen (British patent 30,397, Dec. 29, 1909) consists of a cylindrical chamber which is made in three sections and mounted horizontally. The two end sections are fixed, while the middle section may be rotated. The lamps employed are fixed to a central rod passing through the chamber. The liquid to be sterilized is admitted at one end of the chamber, the central section is then rotated rapidly so as to cause the liquid to recede from the lamps and form a layer round the walls of the section, leaving a space between the lamps and the inner surface of the liquid. Instead of rotating the section, a propeller may be provided in the chamber to attain the same object. If a sufficiently high speed be imparted to the liquid, the pressure in the space between the lamps and the liquid will be practically nil, but with a lower speed, air may be admitted to fill the space. The liquid leaves the apparatus at the end opposite to the inlet. The apparatus may also be mounted vertically.

Henri Helbronner and von Recklinghausen (United States patent 1,151,267, August 24, 1915, and 1,193,143 August 1, 1916) describe an apparatus for treating liquids such as water which consists in a series of drawers or trays arranged in a zig-zag manner which allows an apparatus of comparatively small size to expose a large amount of water to the action of the light derived from a single lamp. It is also proposed to pass the water during the sterilization period through a series of drawers, a part of which are exposed to the light and a part being kept entirely dark. It is claimed that the best effects were obtained when the liquid was exposed for only about one-fourth of the time of its total passage through the apparatus.

For treating water and other liquids with ultra violet light, Henri, Helbronner and von Recklinghausen, (United States patent 1,150,117, August 17, 1915) describe a process for controlling the amount of liquid to be passed through the sterilizing chamber. For example, if the lamp becomes extinguished for any reason, the water is shut off, or on the other hand when the lamp is first started it takes some little time before it has reached its full power. In this case the water is allowed to flow slowly when the lamp is first put in operation, the rate of flow increasing until the control valve becomes wide open when the lamp has reached its maximum efficiency.

Sterilization of Milk.

For treating liquids which are rather opaque to the ultra violet rays, Henri, Helbronner and von Recklinghausen, (United States patent 1,068,898, July 29, 1913) propose the use of a rotating wheel or band to carry very thin films of liquid for exposure to the action of ultra violet light. In treating milk, it is stated that where the scraper removes the liquid from the roller after being treated, particles of butter are quite likely to be formed and these may cause difficulty later. Several modifications of scrapers, rollers, etc., to remove these particles of butter are shown. In one case the milk is removed from the roller by a jet of air, it being claimed that in this case no butter is formed. It is also proposed to use a second cylinder rotating in the opposite direction for removing the milk after sterilization.

Further modifications of apparatus for treating milk and other liquids are described by Henri, Helbronner and von Recklinghausen (United States patent 1,052,818, Feb. 11, 1913) in which the roller picks up a thin film of liquid, exposes it to the action of ultra violet light and in turn delivers it to a second roller, which gives it a further exposure. It is also proposed to arrange these cylinders in a gradually descending plane and then to expose in a gradually rising plane until the sterilized liquid is delivered at a point approximately equal to the point of entry. In such an apparatus the lamp is located in the center of this V-shaped receptacle, whereby its full efficiency is obtained.

Various other forms of apparatus are described by Helbronner and von Recklinghausen (British patent 12,948, May 27, 1910, and 18,458, Aug. 4, 1910) for treating opaque liquids with ultra violet rays, the essential feature of each modification of the apparatus being that the liquid is caused to pass before the lamp in the form of a thin layer. For this purpose the liquid may be passed through a shallow channel or tube, preferably of circular cross section, the lamp being suspended in the center of the circular vessel. The side of the channel opposite the lamp is constructed of quartz or of glass which is permeable to the rays. This side of the channel may be cooled by means of sprays of water. The cooling may also be effected by filling the space between the lamp and the channel with water. The liquid may be passed between plates which are permeable to the rays, or a number of flat channels may be employed.

In a process for sterilizing liquids, Henri, Helbronner and von Recklinghausen (United States patent 1,124,737, January 12, 1915) expose the liquid to be treated in thin films, which are produced by the force of adhesion. It is claimed that opaque liquids similar to milk do not form sufficiently thin films to enable them to be efficiently sterilized when the force of gravity alone is relied upon to produce the films. In the apparatus described a thin film liquid is caused to travel upward on the inside of a hollow cylinder within which the ultra violet lamp is located. The liquid is delivered into this exposure chamber from a series of jets near the bottom of the cylinder. The latter is rotated in such a manner as to carry the thin film around the periphery and the film is scraped off upon completing the circuit. A device to cool the sterilized liquid is used in connection with the scraper.

(To be continued in the September issue.)

Addresses to Feature Chemical Exposition Week of September 24

Manufacturers, works managers, chemists and engineers all over the country are taking a very active interest in the Third National Exposition of Chemical Industries to be held in the Grand Central Palace, New York, week of Sept. 24, 1917.

The success of the former Expositions have been heralded in European countries. This has stimulated these countries to seek a better knowledge of the remarkable growth of the American Chemical Industries.

The U. S. Government, through the Bureau of Soils, will be represented and will have an exhibit illustrating the fertilizer situation, and more especially American sources of potash.

The program of the Exposition in part in the last issue bids fair to attract much attention. In one phase it will discuss the foreign trade opportunities that the American manufacturer now has presented to him, and how to gain and hold those markets. Another phase of the program covers the work of some of war councils. It will be remembered that at the first Exposition Mr. Howard Gross was one of the speakers and there proposed a Governmental Tariff Commission; the appointment of that committee by the President is but one of recent moment and it is an interesting thing to learn how that committee will operate. Dr. Grinnell Jones, of Harvard University, who has been selected as Chemist to the Commission, will be one of the speakers. It is not unlikely that Dr. F. W. Taussig, the chairman of the Commission, will be another speaker to enter into the national operation of the Commission for all the industries, while Dr. Jones' discussion will be confined to the chemical phases of the Commission's work. It is certain that these addresses will be of great importance to the Chemical industries, supplying them with much valuable information as to what they may expect, and as to how they could assist the Commission making its work more thorough, to have a stimulating effect upon the productiveness of the American Chemical Industry.

There will be a symposium upon the national resources where men thoroughly familiar with them will discuss their opportunities and how great industries can be built therefrom.

The tentative program as now set forth is as follows:

Monday, Sept. 24th—Opening Day.
  Opening addresses by Dr. C. H. Herty, Dr. Julius Stieglitz, Prest. American Chem. Soc.; Dr. C. G. Fink, Prest. Amer. Electrochemical Soc.; Dr. G. W. Thompson, Prest. Amer. Inst. of Chemical Engineers.
Tuesday, Sept. 25th—
  Prof. M. T. Bogart, Chairman, Chemical Committee, National Research Council, "The Operation and Work of the National Research Council for the National Weal."
  Dr. Grinnell Jones, "The Tariff Commission and Its Operation With Reference to the Chemical Schedule."
Wednesday, Sept. 26th—
  W. S. Kies, Vice-President National City Bank, "The Development of Export Trade With South America."
  Dr. L. H. Baekeland, Naval Consulting Board, "The Future of the American Chemical Industry."
  Meeting of the Technical Association of Pulp and Paper Industry.
Thursday, Sept. 27th—
  Symposium on National Resources for Chemical and Allied Industries, participated in by
  Mr. C. H. Crawford, Assistant to President of Nashville, Chattanooga & St. Louis Ry.
  Mr. V. V. Kelsey, Chemist-Industrial Agent, Carolina, Clinchfield & Ohio Ry.
  Dr. E. A. Schubert, Mineralogist-Geologist, Norfolk & Western Ry.
  Dr. T. P. Maynard, Mineralogist-Geologist, Central of Georgia Ry. and Atlantic Coast Line Ry.
  Dr. J. H. Watkins, Geologist, Southern Ry.
  Meeting of the American Institute of Chemical Engineers.
Friday, Sept. 28th—
  Meeting American Chemical Society, New York Section. Papers to be announced later.

The motion picture program will be announced later, though the following firms have placed their films at the use of the exposition managers: The American Cyanamid Co.; Barber Asphalt Paving Co.; E. I. DuPont de Nemours & Co.; General Electric Co.; Eagle-Picher Lead Co.

CONTENTS, AUGUST, 1917

Coal-Tar Chemistry 201
Edited by Thomas H. Norton, Ph.D., Sc.D.

Under which is included:

EDITORIALS:

The Organization of National Industrial Research 201
A New Factor in the American Dyestuff Industry 204
Government Activity in the Field of Color...... 205
Phenol from American Coal-Tar.............. 206
Annatto from Porto Rico..................... 206
The American Supply of Toluene............. 207
Situation of the Leading German Artificial Color Company 208
Export Licenses 208

COAL-TAR CRUDES:

The Determination of Phenol in Crude Carbolic Acid and Tar Oils......................... 209
John Morris Weiss and C. R. Downs.

COAL-TAR INTERMEDIATES:

Differentiation of the Two Naphthols by the Aid of Sulfotitanium 220
Manufacture of Phosgene................... 220
Quantitative Estimation of Picric Acid........ 220
3-Nitro-1-amino-benzene-6-sulfonic Acid 220
Aromatic Amido-Oxy-Compounds 221
Amino-anthraquinone 221
An Improved Method of Separating Sulfonic Acids 221

ARTIFICIAL COLORS:

The Evolution of Coal-Tar Colors............ 221
The Physical Basis of Color Technology........ 223
Government Control of the British Dyestuff Industry 224
A New Class of Yellow Azo Colors........... 224
A New Series of Sulfur Yellows.............. 224
New Azo Colors for Use on Vegetable Fibers.. 225
Color Lakes Derived from Complex Tungstic Acids 225
New Wool Disazo Dyestuffs.................. 226
The Use of Phosphomolybdic Acid in Producing Color Lakes 226

NATURAL DYES:

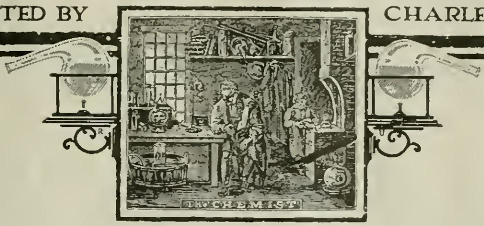
The Art of Dyeing 227
Clement Bolton.
Color Trade Journal, Vol. 1, No. 1, August, 1917. 229
Disastrous Conflagration in the Factory of the Seydel Manufacturing Co.................. 230
Explosion in the Beckers Works.............. 230
Explosion in the Works of the Midvale Co...... 230

CURRENT WHOLESALE PRICES OF COAL-TAR PRODUCTS:

Crudes, Intermediates and Explosives, Synthetic Medicinals, Flavors and Perfumes, Photographic Developers, Artificial Colors......... 230
Natural Dyestuffs, Dyewoods and Raw Materials, Extracts, Dyeing Accessories................ 231
Imports and Exports of Coal-Tar Products and Natural Dyestuffs 231
Ultra Violet Light: Its Application in Chemical Arts. Part VI.......................... 232
Carleton Ellis and A. A. Wells.
Addresses to Feature Chemical Exposition of September 24 235
Table of Contents.......................... 236
Chemical Investigation, Efficiency and Control... 237
Conducted by Charles B. Davis.
Distillates: News Notes of Chemical and Allied Industries 238
Foreign Trade Opportunities 239
August Prices of Chemicals, Etc.............. 240

CHEMICAL INVESTIGATION
EFFICIENCY & CONTROL

CONDUCTED BY CHARLES B. DAVIS. F.C.S.



ALL classes of work covered by the following subjects will be done for readers of "The Chemical Engineer" through this department by Mr. Davis: Special research of every description; analysis and reproduction of any commercial product; prevention of waste and utilization of by-products on the most economical basis; valuation of raw materials; food analysis, and disputed points in regard to adulteration, labeling, and the enforcement of pure food laws; bacteriological and enzymatic examinations, including fermentation tests, pure yeast cultures, beverages of all kinds; development of chemical inventions and industrial processes; examinations and advice on special machinery.

Inquiries of a minor character will be answered on this page, while major matters involving personal investigations, analyses, etc., will, if desired, be treated confidentially through the mails. All questions, materials for analysis, or letters leading to the opening of negotiations for special work will receive prompt attention if addressed to

CHARLES B. DAVIS,
Care of "The Chemical Engineer," 118 East 28th Street,
New York City.

A. S. T.—Your inquiry regarding Argon has been looked into very carefully, and I am in a position to report as follows:

Discovered by Rayleigh & Ramsay in 1894.

Vapor density (0-16)	19.67
Atomic weight	39.90
Condenses to colorless liquid and boils at	—186.90
Air contains—volumes	0.9

By cooling with oxygen at 50.6 atmospheres it solidifies.

Removed from nitrogen by passing over red-hot magnesium, which absorbs the nitrogen and leaves the Argon.

Molecular Heat	2.50

which proves that Argon has only atom in its molecule and weighs 40.0.

	*Helium	Neon	ARGON	Krypton	Xenon
Density	1.98	9.97	19.96	40.88	64.
Atomic Weight	4.0	20.0	39.9	81.8	128.0

(All five discovered by Ramsay.)

W. B. P.—The sample of maple syrup taken by me from your manufacturers' last shipment gave the following results upon chemical analysis:

	per cent.
Solids by refraction	68.00
Polarization direct (V)	+57.00
Polarization invert (V26C)	—21.00
Polarization invert (V87C)	0.00
Lead number	0.79
Ash	0.46
Reducing sugar before inversion	5.98
Glucose	0.00

These figures point to added cane sugar; therefore it is an adulterated article. The cane sugar has been added to lower, reduce, and injuriously affect its quality and strength. It is also misbranded for the reason that the article is an imitation of pure Vermont maple syrup.

M. C. S.—Your letter regarding the waste products you are sending me for analysis has been received. Just as soon as the samples arrive I will start the investigation to ascertain in what manner and what industries these materials can find a profitable outlet.

I would recommend that you read the article by G. R. Tuska on "Improvements in Waste Disposal Plants," in the Feb.-Mar. issue of this journal.

G. A. H.—The color of your starch is entirely due to its reaction. I also wish to draw your attention to its high content of moisture, which, if not reduced, will favor mould growth. I strongly recommend that you remove this moisture by a gradual increase of temperature so as to prevent gelatinization.

G. X. L.—You are adding too high a percentage of water to your white paint, which is greatly impairing its drying qualities.

You are perfectly correct in your preference for zinc white over lead oxid when used in chemical laboratory painting since the latter would rapidly discolor from the fumes.

M. I. O.—Aseptic autolysis of your beef during cold storage will not occur if you prevent bacterial action, and see that the most favorable conditions prevail. Autolysis is caused by the action of enzyms occurring naturally in the beef and mainly in the muscular tissue. If you will inform me just when it will be convenient to take the samples, I will proceed with the bacteriological control experiments and ascertain the direct cause of your trouble.

Charles B. Davis.

Those whose inquiries to this department have not as yet received attention must bear in mind that unless replies by mail ar specifically requested, communications can only be considered in the order of their receipt.—Editor.

DISTILLATES

News Notes of Chemical and Allied Industries

$3,000,000 Chemical Corporation.

Under the laws of Delaware, the Virginia Consolidated Chemical Corporation has been incorporated with a capital of $3,000,000 to conduct chemical works of all kinds. F. D. Buck J,. D. Frock and K. E. Longfield are the local Wilmington, Del., incorporators.

Chlorine Products, Dyes, Chemicals, Etc.

The Virginia Chlorine Products Corporation has been incorporated under the laws of Delaware with a capital of $1,500,000, to manufacture all kinds of dyes, chemicals, etc. The incorporators are C. J. Kulberg, New York; H. Van Arsdale, Newark, N. J., and D. A. Woodcock, Passaic, N. J.

Chemicals and Dyestuffs.

With a capital of $200,000, the Consolidated Core and Chemical Co., Inc., has been incorporated under the laws of New Jersey, to manufacture chemicals and dyestuffs. C. F. Fuehrlein, 122 Hudson St., New York City, represents the new firm.

To Export and Import Chemicals.

The Orient Merchandise Company, Ltd., Manhattan, has been incorporated under the laws of New York to export, import and deal in chemicals. The capital is $25,000 and the incorporators are I. Bergman, F. Friedman and S. R. Rhodes, 38 Park Row, New York City.

Will Deal in Chemicals.

The Thomas & Betts Company, Elizabeth, N. J., has been incorporated under the laws of that state with a capital of $300,000, to act as merchants and deal in chemicals. The incorporators are Robert McK. Thomas, Mendham, N. J.; Hobart D. Betts, Englewood, N. J., and Adnah McMurtrie, New York City.

Tanning Firm Incorporated.

The Alliance Commercial Company, Inc., Manhattan, has been incorporated to carry on a business in hides, skins, leather and as tanners. The capital is $5,000 and the incorporators are M. S. and R. Reiler and M. Spiro, 448 Fifteenth St., New York City.

Coloring Matter for Brewing.

24803—An association in England wishes to purchase malt, barley, glucose, chocolate in bars, beer in casks and bottles, coloring for brewing, milk in tins, and fodder for cattle. Quotations should be made c. i. f. French or British ports, also c. i. f. Haifong, French Indo-China. Payment will be made by cash against documents. Reference.

Drugs and Chemicals.

The Warren Products Co., Inc., Manhattan, chemicals and drugs, has been incorporated under the laws of New York, with a capital of $10,000, by F. L. Cramer, O. K. Hill and H. R. Harrison, 120 Broadway, New York City.

Chemicals and Medicinals.

The Lister Aseptic Company, Manhattan, has been incorporated under the laws of New York, with a capital of $5,000, to manufacture chemicals for medical and other purposes. The incorporators are J. H. Deats, R. Reed and W. Wilson, 89 Macon St., Brooklyn.

Glue, Gelatine and Mica.

National Gelatine & Glue Works, Inc., New York City, has been incorporated with a capital of $5,000 to manufacture glue, gelatine and mica. The incorporators are A. J. and W. Alexander, 229 West Ninety-seventh Street.

Fertilizer, Ammonia and Greases.

Fertilizer and a number of other by-products, which include ammonia and greases, and bone-charcoal for sugar-refining, will form the regular output of the brick and steel chemical plant to be erected, at a cost of $51,000, by the Texas Chemical Company, Houston, Texas.

Largest Paper Mill to Be Erected.

The erection of the largest paper mill in the United States is contemplated by the Sound Paper Company, Seattle, Washington, which was recently incorporated with a capital of $6,000,000. It is estimated that $10,000,000 will be required to build the plant, and as much again for the development of the Sultan water power project, which the city of Seattle has granted the company permission to carry out.

Will Manufacture Coal-Tar Products.

The West Coast Chemical Company, Seattle, Washington, is seeking 25 to 50 acres of land for the erection of a plant for the manufacture of coal-tar products.

$4,000,000 Alcohol Corporation.

The International Alcohol Corporation has been incorporated under the laws of Delaware with a capital of $4,000,000 to manufacture alcohol from sawdust, wood waste, celluloid and other substances. Lewis F. Rebore, Frank Cusick and A. Sheard, all of New York, are the incorporators.

FOREIGN TRADE OPPORTUNITIES

These Opportunities for Foreign Business Relations Are Made Public by the Bureau of Foreign and Domestic Commerce, of the Department of Commerce, Washington, D. C. Names, Addresses and Details May Be Obtained from the Bureau or Any of Its Branches. Refer to the Number of Each Opportunity and Place Inquiries for More Than One on Separate Sheets.

Fumigating Apparatus; Paper Towels.

23944.—A firm in Canada is in the market for hand and small portable spraying devices for oils, liquid-soap dispensers, disinfecting devices and deodorizers, fumigating apparatus and materials, and folded paper towels. Quotations should be made f. o. b. port of shipment. Correspondence may be in English. Reference.

Washing Soda and Soap.

24082—A firm in Dutch Guiana, with representatives in the United States, desires to receive quotations from American manufacturers and exporters of green or soft soap in two and one-half to three-pound bars, and washing soda.

Medium Priced Writing Paper.

23948.—A merchant in British East Africa wishes to buy medium priced ruled paper in pads of 100 sheets; about 50 gross pads are needed annually; about 3,000 reams of ruled legal cap writing paper; about 20,000 packages of note writing paper, 100 sheets to a package; about 50,000 thin blue and white envelopes; and about 300 gross of large and small copying pencils. Quotations should be made c. i. f. destination. Payment will be made by sight draft. Goods should be packed in extra strong waterproof cases. Correspondence may be in English. Reference.

Soaps.

24050—A firm in British Guiana is in the market for all kinds of soap, especially low and medium priced laundry soap. It also desires to entertain an agency proposition. Quotations should be made f. o. b. New York. Terms desired are 60 days' credit or draft against documents. Correspondence may be in English. Reference.

Sulphite Pulp.

24563.—A man in Italy wishes to purchase 1,000 tons of bleached and 2,000 tons of unbleached strong, fibered sulphite pulp, perforated dry, 10 per cent. air moisture. Quotations should be made c. i. f. destination per ton of 1,015 kilos. Payment will be made by bank credit. The pulp should be baled and wrapped with jute. Correspondence may be in English. Reference.

Oils, Drugs and Chemicals.

24778—A company in Sweden desires to be placed in communication with American manufacturers and exporters of raw materials for the textile, soap, paper, and margarine industries, cotton, wool, rubber, oils, metals, coffee, cocoa beans, spices, dried fruits, sirups, glucose, grain, mill products, lard, tallow, chemicals and drugs, resin, shellac, paraffin, raw hides and leather for shoe manufacturing, yarn, thread, wool, linen and cotton cloths, knit, tricot, and hosiery goods, novelties, automobile tires, etc. References.

Dyes, Oils and Varnishes.

24822—Quotations are desired by a firm in Italy for dyes, oils, varnishes, etc. A complete list of goods desired may be had on application to the Bureau or its district offices. Correspondence may be in English. Reference.

Aniline Oil; Coloring Substances.

24906.—Purchase is desired by a man in Italy of coloring substances generally, including aniline oil; leather for shoes (soles and uppers), and leather for automobile upholstering. An agency for these goods is also desired. Correspondence must be in Italian, Spanish, or French. Prices must be quoted to include packing, net weight, in Italian lire. Reference.

General Chemical Products.

25000.—Chemical products are desired by a large firm in Italy. A list of the chemicals desired and other information may be had on applicationt to the bureau or its district offices.

Carbolic Acid, Formaldehyde, Etc.

25210.—An agency is desired by a man in Italy for the sale of chemical and pharmaceutical products, especially carbolic acid, formaldehyde, salicylate salol, etc.; groceries, cocoa and cocoa butter, and mineral oils. Correspondence should be in Italian or French. References.

Chemical Products and Drugs.

25049.—A man in Guadeloupe desires to be placed in communication with manufacturers of chemical products and drugs. Correspondence should be in French.

EDITORIALS

The Purity and Strength of American Artificial Colors.

It is an almost every-day occurrence to encounter, in the daily journals and in the textile trade press, paragraphs tending to lower in the general estimation the quality of American-made dyes. Here is a typical example:

> "In spite of the progress reported in the manufacture of fast dyes in this country, retail stores are receiving complaints almost daily in regard to garments that have been injured or wholly ruined by colors that would not stand washing. A recent case is that of an expensive wash silk waist that was trimmed with hand-embroidered designs in colors. The color of the waist 'stood up' all right under the laundering, but the hues of the embroidery yarns were so intermingled with it that the waist looked like a kind of modern Josephs' coat. In another case perspiration took the dye out of the lining of a piece of summer fur and transferred it to the neck and waist of the wearer with generally disastrous results. Complaints of 'fugitive' colors in children's garments are frequent."

It is a patriotic duty to protest against this tendency to belittle the quality of the artificial colors now made in this country.

It is well known to every tinctorial chemist, and probably to most American dyers, that the colors now made in the United States are neither better nor worse than the corresponding colors of German or Swiss origin. They are simply identical, as far as dyeing properties are concerned. They may contain per pound more or less of the distinct coloring principle in question than the brands of foreign make, to which our dyers were accustomed before the war, just as there is great diversity in the concentration of the different types of a given dye made by any foreign or domestic manufacturer.

In regard to fastness towards light, washing, etc., the inherent properties of any current color remain the same whether it is made in Europe or America. The leading, reputable firms, manufacturing dyes in this country, are as scrupulous in assuring the purity and correctness of the colors sold under given designations as are their European rivals.

The cause of the frequent complaints referred to above is the failure of dyers to make use of dyes guaranteed by firms of recognized standing.

The general public fails to grasp the fact that the great mass of artificial colors possess but relative degrees of fastness to light, to soap, to acids, etc.

They are sold for specific purposes with a full knowledge by both seller and consumer of the limitations under which any color labors.

It is the business of the dyer to employ only such colors as possess the requisite degree of fastness for the materials to be dyed, as normally there is no difficulty in this connection. With the still existing shortage of many dyes, not yet made in this country, there is a constant temptation to use colors of a more or less fugitive nature, in order to meet the demands of fashion. There is nothing wrong in this practice, if the purchasers of fabrics or articles so dyed are clearly and adequately informed of the lack of fastness, so that they may be upon their guard with regard to the use of the same.

In the interest, however, of the good name of our American dyes, a determined effort should be made to have the relative fastness of the colors employed upon textile fabrics and similar wares adequately indicated upon the same. When the struggle begins to maintain the credit of our domestic colors against the effort to supplant them by foreign makes—and the time may not be far distant—it will be a tremendous asset to have the ordinary consumer convinced, in advance, that American manufacturers can furnish just as reliable dyes as those made upon the banks of the Rhine.

Death of Adolf von Baeyer.

The death at Munich, on August 23, at the ripe age of 82, of Professor Adolf von Baeyer, robs chemistry of one of her foremost leaders, one who has conspicuously directed the course of evolution of the coal-tar colors industry.

Baeyer was born in Berlin, October 31, 1835, the son of General Johann Jakob Baeyer, of the Prussian army, distinguished in the geodesy of Germany, and the first president of the Geodetic Institute of Berlin, created in 1869.

His university studies were pursued at Heidelberg, Ghent and Berlin. At Berlin he took the doctor's degree in 1858. He had already begun to specialize in organic chemistry, then beginning to claim an increasingly independent status in the university curriculum, largely as the result of Liebig's pioneer work.

In 1860 he was admitted as docent in organic chemistry to the teaching force of the Berlin University, and shortly after extended his courses to the Gewerbeakademie. In 1866 his marked ability was rewarded by promotion to the rank of extraordinary professor in connection with which he later had charge of the courses in chemistry at the Kriegsakademie. His marriage to Lida Bendemann, daughter of a prominent mining director, took place in 1868.

During this period Baeyer's laboratory at Berlin became an active center of research, and attracted many bright young chemists. The problems of the aromatic series, and especially of its tinctorial compounds assumed a dominant position. It was under Baeyer's guidance, in 1868, that Graebe and Liebermann carried out their classic synthesis of alizarin, and simultaneously paved the way for the discovery and utilization of a host of anthracene derivatives.

The Franco-German war came, and ushered in a new German Empire. One of the immediate results of the annexation of Alsace was the decision to create at Strassburg a university of the first rank. Brilliant and promising men were called to fill the chairs. In 1872, Baeyer was made ordinary professor of chemistry. Students quickly thronged his lecture room and laboratory.

The stay at Strassburg was however somewhat brief. Justus von Liebig, reverently regarded as Germany's foremost chemist, passed away and his chair at the University of Munich became vacant. The choice of a successor fell upon Adolf Baeyer, and time has amply vindicated that choice. In 1875 he removed to Munich, where a magnificent, new and modern laboratory was constructed after his plans. Here his lifework was carried out, and here he died. Students came from all parts of the world to Munich, as freely as when von Liebig was the presiding genius. In 1885 he was raised to the ranks of the hereditary nobility, as was the case with Liebig before him. Honors were showered upon him from all sides, and his name was placed upon the rolls of numerous academies and learned bodies. In 1881, the Royal Society of London conferred upon him the Davy medal; the French Academy of Science made him a foreign member in 1886, and in 1905 he received the Nobel prize for chemistry.

The researches of von Baeyer were extremely varied and numerous. Over 300 studies were published by him in the *Annalen der Chemie* and in the *Berichte* of the German Chemical Society, in the development of which he was actively interested from its origin in 1869.

He may fairly be regarded as the leading chemist of his day in organic synthesis, and this was the dominant note of most of his investigations. Some of the lines which he pursued were remarkably prolific of results, and opened paths followed up by many of his contemporaries. This was in a marked degree the case with his studies on condensation products, especially of aldehydes with hydro-carbons and phenols. Otto Fischer's discovery, in 1877, of Malachite Green, for instance, was made in the Baeyer laboratory.

In this field von Baeyer's most notable services, and those with which his name will be most closely associated, were rendered to the coal-tar color industry.

In the discovery of the wonderful possibilities of the phthaleins as sources of tinctorial substances, he made it possible to create a group of coal-tar dyes, resembling the alizarin group, and the various vegetable colors, apart from indigo, in the absence of nitrogen in the molecule.

His discoveries, in 1871, of phenol-phthalein, of fluorescein or uranin, of coerulein and of gallein (obtained from pyrogallic acid and not a coal-tar derivative), were not only in themselves most valuable contributions, but they paved the way for others in the years immediately following to quickly enlarge the group. Noteworthy was the discovery by Caro in 1875, of eosin. In this latter case, and in other closely allied instances, the exhaustive theoretical studies of von Baeyer formed the fundamental basis for inventive skill to extend with certainty and with rapidity the scope of its efforts. In later days faster and almost equally brilliant azo colors have displaced for many purposes eosin and other members of the group. A considerable demand, however, still exists. The discovery and introduction into tinctorial chemistry of the phthalein colors will always be regarded as a notable milestone in the evolution of coal-tar chemistry.

Of still greater and more lasting value are the marvelous series of studies in which von Baeyer disclosed the chemistry of indigo. With the help of finely trained assistants, he traced all the relationships between the products of the decomposition of indigo and simple constituents of coal-tar. The transformations, by successive steps, of the latter to isatin and to indole were patiently worked out, and the constitution of the indigo molecule clearly shown. These studies lasted from 1865 to 1878. During this period, but in a much shorter period of time, Graebe and Liebermann in his laboratory effected the synthesis of alizarin and the manufacture of the artificial product was made a commercial success. The realization of the same problem in the case of indigo was beset by far greater difficulties. It was not until 1880 that von Baeyer perfected the various steps connected with the synthesis of indigo from o-nitro-cinnamic acid, and that he was able to present it as an industrial process and secure patents. Technically the method was a success, but it was not possible to reduce the costs of production to the point allowing competition with the natural product. A fundamental difficulty was the price, and the limited amount available at that time, of toluene, from which cinnamic acid could be manufactured. A vast amount of work still remained to be done. In 1890, Heumann introduced his synthesis, based upon the use of phenylglycocoll-o-carboxylic acid, and soon after it was found feasible to use cheap naphthalene instead of toluene as the initial material. By 1897 it was possible to introduce artificial indigo upon the world's markets, and at the opening of this century it practically dominated the situation. The famous "Badische Co." did much to bring about the successful result. Its facilities were placed at the service of Prof. von Baeyer for years, and its chemists elaborated and rendered practicable the many individual features of the synthesis. It is stated that the company expended, all told, upon artificial indigo about $5,000,000 before a single pound was placed upon the market.

While vast sums were thus sunk, and scores and scores of chemists contributed each their mite to the final success, the name of von Baeyer, will always be most closely associated with this great triumph of synthetic chemistry. His profound and varied studies revealed every feature of the problem to be solved, and he first bridged all of the intervening gaps between coal-tar and pure indigo, leaving to others to complete the more purely economic details.

During the later years of his life, stereochemistry attracted much of his attention. In this connection he advocated the "centric" view of the constitution of the benzene ring.

Von Baeyer was a man of imposing personality, and of numerous friendships. Many Americans and many English chemists were trained in his laboratories, and owe much to his inspiration and companionship. No public utterance has been made by him since the outbreak of the present conflict, but it has probably caused him many a heart-wrench, as it would to August von Hoffmann, had he survived to our day. Both were connected by a multitude of ties with the men of science in all lands.

Professor von Baeyer had three children, one daughter and two sons. Of the latter, one has devoted himself to medicine, the other to physics. It appears to be exceedingly rare in Europe for chemical ability of a high order to be transmitted from father to son.

Co-Operation in Research.

There is continued discussion in England of the need of a much greater degree of co-operation in the chemical industry than has hitherto been the case. It is felt by many that the efficiency of the industry, as a whole, has suffered seriously from the individualistic policy which has been so marked in the past.

The questions of analytical control and standardization, and especially the all-important matter of research, as ensuring future healthful progress and the ability to meet aggressive foreign competition, are frequent topics of debate at all gatherings of technical men.

At the recent annual meeting of the Society of Chemical Industry Mr. Herbert W. Rowell emphasized the value of such highly organized facilities as are now multiplying in the United States, dwelling especially upon the work of the Mellon Institute in Pittsburgh.

Mr. Rowell feels that the British coal-tar industry is bound to face both a commercial and a technical revolution after the war, and urges prompt preparation. His argument applies to certain conditions in the American industry, as will be seen from the following extract:

> If the coal-tar interests can have commercial agreements as to raw materials, sulphate of ammonia, and creosote, why not in standard tests and products and in research and development of the trade. The tar producers and manufacturers of crudes and intermediates could subscribe, say, in proportion to their capital or turnover, to institute a central laboratory and experimental works while control testing and efficiency of existing plant would remain a matter for the attention of the individual works. This laboratory could have two functions, one an analytical department for devising specifications and standard methods of analysis and acting as a referee laboratory for the trade, and the other a research department with an experimental works and staff of chemical engineers attached to it.
>
> The specifications and tests devised by the analytical department would be common property, and would link producer and consumer and would help stabilize the trade, while the results of experiments, patented processes and plant, and other profits of the research department would be the property of the subscribers to the scheme. If it were made into a limited company with a scale of payments to it for the use of ideas evolved, the commercial aspect of the laboratory could easily be solved.
>
> The central analytical laboratory idea offers no difficulty, the cost would be small, and the results

of distinct value, but unless the trade is closely allied by commercial agreements, then the question arises as to what work could be undertaken by a central research department. A phase of work of general importance in which business interests could not clash is in raising the demand for and consequently the price of tar products and in meeting competition from other trades and nations.

If a research department could make pitch equal to natural bitumen, tar oils into fuel, and lubricant equal to petroleum oils, or discover a use for creosote oil equal to the present demand for timber preservation—and these things are by no means impossible,—it would cover its cost many times over.

The tar works is the proper place in which to make dyestuff intermediates as it economizes capital, material, transport, and labor. Many concerns have now nitric acid, oleum, nitration, sulfonation, and acid recovery plants, and have only vague plans for their use after the war.

Chemical and chemical engineering research is necessary before these plants can be utilized and the intermediates trade developed. A central organization working for the trade in general would produce cheaper, better, and quicker results than a number of badly equipped laboratories inadequately staffed, which is the best for which we can hope if the home manufacturers indulge in civil war while the German gathers in the trade again.

Other matters of a non-competitive nature, which might be taken up are the carriage of dangerous goods, better and cheaper packages, safety measures against fire, explosion, and industrial disease, and fuel economy. If an organization got as far as this, it would certainly develop into a full combination of technical interests. It would follow that the methods of distillation and the value and composition of the tar produced, and the possibilities in blast-furnace, producer gas, and oil gas tars are matters for investigation of profit both to producer and distiller.

The time for organization is short, for we expect soon to bring this war to a successful end, and we cannot deprive Germany of her scientific brains and organizing ability. We have immediately to face a commercial war against countries like America and Japan, with capital, scientific organization, and business efficiency, and the issue rests mainly with the directors of our engineering, chemical, and textile industries.

We look for some help from Government departments and committees, from scientific societies, from preferential and protective tariffs, from pure research in the universities and better education, but if the manufacturers and particularly the average and small-sized works, do not evolve their own salvation by the prompt adoption of scientific research and control, coupled with scientific management and business methods, the issue is certain and disastrous.

Artificial Phenol.

Nothing contributes more to the general confidence in the ability of our American chemists to rapidly and successfully solve big problems than a glance backward over the establishment in this country, since 1914, of the manufacture of synthetic phenol on a gigantic scale. A score or more of large plants are now producing it regularly in great quantities, chiefly for use in the manufacture of picric acid for war purposes.

The pioneer in the industry, however, was Thomas A. Edison. He it was who first comprehended the situation, saw it in a correct perspective, and took the necessary steps to insure a supply for the nation's needs. We were consuming normally a considerable amount of phenol, chiefly as a disinfectant and for antiseptic purposes. There was a certain amount needed in the arts, notably for the manufacture of the records for phonographs, graphophones, and the like.

Every pound of the supply came from Europe. Once the war was fairly started, the available stock was quickly commandeered by the belligerent governments. The price in the United States mounted, in a short time, from 9 cents per pound to $1.50. Prompt action was needed unless a variety of interests should suffer seriously. It was the quick resolve of Mr. Edison to create the synthetic manufacture of phenol from benzene which relieved the situation. In a short time he had demonstrated the ease and relative cheapness with which the hydrocarbon can be transformed into phenol, and provided the requisite supplies for sanitary and hospital purposes. Then came the insistent demands from abroad for picric acid. American firms were able to enter upon contracts, duplicating in their works the finely perfected system for the synthesis of phenol, equipped early in 1915 at Orange, N. J., by the Thomas A. Edison Co.

To-day the works at Orange are furnishing regularly 3,000,000 lbs. of phenol each month. So completely has the process been standardized that Mr. Edison has no intention of abandoning it when the war ends and normal conditions return. He is confident that he can manufacture artificial phenol at a cost no higher than that involved in the separation of phenol from coal tar and its complete purification.

We have no reason to wonder that Mr. Edison was, almost automatically, made the head of the Advisory Committee, called into existence by the Secretary of the Navy, over a year ago, when the possibilities of war became evident.

Women and Dyestuffs.

In another column we give details regarding the discovery of a new vegetable coloring material by Mrs. E. O. MacDonald, of St. Regis Falls, N. Y. There is a somewhat unusual degree of interest attached to this discovery of the dyestuff in autumnal leaves. As far as we know it is the first recorded instance in which the world is indebted to a woman for enriching its list of colors, natural or artificial.

It is, of course, not improbable that women may have contributed largely, during the ages, to the detection of the tinctorial value of various barks, leaves, fruits, etc., from which coloring matters could be extracted to use on textiles, basket work, and the like. But here we witness a woman, and it is pleasant to add, an American woman, carrying out the entire sequence of operations involved in the discovery of a new dye, the observation of color being crudely imparted, the logical deductions as to its source and nature, the experimental separation of the coloring principle, the painstaking and exhaustive determination of the methods of successful application!

Chemistry is a science in which women have, thus far, contributed but little to the main lines of progress. A single chemical element has been discovered by a woman. This was radium, discovered by Madame Curie, of Paris, co-operating, it is true, with her husband, but recognized as fully his equal in all that pertains to the successful revelation of the nature and properties of the elusive element, and the painstaking victory over a multitude of complex difficulties.

No woman's name has been associated with any of our synthetic dyestuffs. Now that young women are found in such numbers in our chemical laboratories, and are doing such faithful work on chemical teaching staffs, it is to be hoped that some one will take up the investigation of "gold leaf," as Mrs. MacDonald's new color is termed, and work out its constitutional formula. This has been done for the more important natural colors. In two cases the determination of the constitution paved the way for the synthetic preparation of the dyestuffs, and the world was enriched by artificial alizarin and artificial indigo.

It is highly probable that we have here to do with a combination of tannic acid and an aromatic complex allied to quercetin, morin or fisetin.

The valuable work of Koptanecki, who has analyzed and synthesized several important vegetable colors, can well serve as a model in this field.

Swift Expansion of the American Manufacture of Coal-tar Colors.

In another section we reproduce in full a most interesting summary by the Bureau of Foreign and Domestic Commerce, showing the present status of the American dyestuff industry.

We have every reason to be proud of what has been done during the past two and a half years. The statistics, collected most carefully by the Bureau, show clearly that today we are manufacturing coal-tar colors in amount equal to our normal consumption of these products before the war. It is true that we are far from producing the variety, then currently consumed, but that will come in time. It is a grand achievement to have organized so rapidly the plant, equipment and operatives needed to accomplish this work, and it will ever rank among the conspicuous triumphs of American enterprise and technical effort.

Despite the shortness of the period in question there is every indication that the foundation of the new industry have been substantially laid, so as to assure its permanence and its healthful expansion. At first it has developed along lines of least resistance, producing those dyes most largely in demand, and yet involving a minimum of time and effort. Now, each day, almost, witnesses the addition to the list of colors based upon more complex processes of manufacture, and necessitating a higher degree of co-ordination on the part of all factors concerned. With each passing week it becomes possible to meet more exactly and adequately the needs of those consuming colors.

The entrance upon the field of powerful corporations testifies to the confidence felt by capital in the future of the industry. The steps taken by our educational institutions, to provide adequate training for those aiming to become color chemists, give hope that we shall soon have an ample staff of young Americans well equipped to join in the work of making our domestic dyestuff production a powerful factor in the nation's industrial life. Before long they should be able to make themselves felt in contributing distinctly and effectively to the evolution of coal-tar chemistry, and create in our country a recognized center for research and progress in this field of unlimited possibilities.

The Department of Commerce deserves a hearty recognition of its interest in this important question, and of its intelligent and earnest efforts to further in every possible way the magnificent work of American capital and chemical skill in adding a new asset to the nation's wealth.

The Swiss Color Industry.

The abnormal conditions during war time have served to bring out in bold relief the fine organization of the four great dyestuff companies at Basel, and the comprehensive character of their products. Their ability, despite the great difficulty in securing raw material, to export a considerable volume and variety of dyes to this country, as well as to France and Great Britain, has contributed notably to take the edge off from the shortage in artificial colors, felt in all countries formerly dependent upon Germany.

It now appears, according to Swiss journals, that the German dyestuff interests are making the attempt—unsuccessful thus far—to buy outright the works in Basel, and make them an integral part of the German combine. Such a move would mean much both at present and after the war. It is not surprising, therefore, to learn that propositions of a similar nature have been made by British interests. It would certainly be of incalculable value to the British color industry if it could in any way assure the co-operation, at least, of the Swiss industry in its effort to rapidly attain independence from foreign sources of dyes. Switzerland's color industry is based upon an enormous amount of technical and scientific accomplishment, undertaken in the face of serious rivalry, and under severe handicaps, for the little republic is practically destitute of all the raw materials required in chemical industries except salt—and ice! Relatively the Swiss have contributed as much, if not more, than the German chemists to the evolution of the artificial dye industry.

More than once it has been suggested that close co-operation between our American color companies and their Swiss colleagues might be of pronounced mutual advantage. As it is, much of what has been accomplished in our midst is due to the presence of individual Swiss chemists, engaged by those occupied in building up the American industry.

It is highly probable that Switzerland, in the future, even more than in the past, will be a center of active research, and contribute notably to the general progress of tinctorial chemistry. The war has levied already a heavy toll upon the young generation of chemists in Germany, who would naturally form the investigators and inventors of the immediate future. The continuity of research has, likewise, been most seriously interrupted, as the attention of trained experts has been diverted to other fields, with more imperative claims upon German skill and scientific attainment.

All of these circumstances, combined with the admirable organization of the Swiss universities, point strongly to a more pronounced position of leadership in the general evolution of the synthetic color industry, and a rivalry which will be increasingly felt by the hitherto so powerful German interests.

The Reliability of American Colors.

A recent statement by the Director of the Bureau of Engraving and Printing at Washington is full of encouragement to those engaged in building up our American artificial color industry. Hitherto the Bureau has been dependent upon German sources for the colors employed in printing postage stamps, bank notes, bonds, etc. With great difficulty and after much diplomatic negotiation, Director Ralph secured in 1916 a needed supply of artificial colors from Germany. At the time he publicly expressed his doubts of the ability of the young American industry to meet the rigid requirements of the Bureau. The chief trouble was found with the red lakes, of which great amounts are regularly consumed. Crudeness of tint and unevenness of color characterized the products then offered by American manufacturers. The prices quoted were, also, practically prohibitive.

All of this is changed in the short course of a year. Director Ralph now declares:

"We are able to get all the colors we want, and at reasonable prices. I feel that the United States has thrown off the humilitating cloak of dominance, particularly German dominance, and that hereafter we can make in this country all the dyes we need, in whatever quantities we need them and at prices that are fair."

In view of the fact that the chief difficulty a year ago was encountered with red lakes, obtained from aniline, his specific statement concerning this category is most satisfactory. He states: "I am particularly pleased with the reds we have been getting. I believe they are superior in tinctorial strength and in durability and will prove considerably cheaper than the German reds we have been using."

All of this shows that the problems connected with the expansion of our coal-tar color industry are not so complicated but that Yankee pluck, knowledge and skill can solve them, and without much expenditure of time.

One by one the important colors are being introduced and manufactured upon a large scale. The processes and the products are being standardized, and American consumers are rapidly becoming accustomed to the types and degrees of strength provided by American producers.

It will not be long before those dyes, of which relatively small amounts are required, will be tackled in the same manner and be enrolled among the lists of "American colors," of recognized reliability in domestic and foreign markets.

The New Location of the National Aniline and Chemical Co.

Early in August the offices of the National Aniline and Chemical Co., Inc., were removed from 100 William Street, New York City, to 244 Madison Avenue, where they occupy nearly three floors.

This removal is an indication of the general movement of the chemical and dye trade of New York City to locations much farther north in Manhattan than the district occupied for so many years. This movement has been expected ever since the leading textile firms have settled in the district on Fourth Avenue and adjacent streets near Madison Square. As the dealings of the trade are so largely with the textile interests, there is a mutual advantage in occupying the same territory. The "National" is well to the north of the textile center; possibly in the expectation that the latter will continue its northward movement. It is highly probable that its example will be gradually followed by the other prominent firms, catering to the needs of the dyer and finisher.

The well-known firm of Walter F. Sykes & Co., dealers in dyestuffs, representing in the United States the St. Denis Dyestuff & Chemical Co. (Poirrier), of Paris, has been dissolved by mutual consent of the partners. Mr. Walter F. Sykes continues the business at 85 Water St., New York City, and has a factory at Bayonne, N. J.

Dr. C. G. Storm has accepted a position as consulting chemist for explosives with the Ordnance Bureau of the War Department, at Washington. For over two years Dr. Storm has occupied an important post with the Aetna Explosives Co. Prior to 1915 he was connected with the Bureau of Mines, and specialized on coal-tar explosives.

COAL-TAR CRUDES

The Manufacture of Anthracene.

There is a very marked hesitancy on the part of American manufacturers of coal-tar products, in extending their operations to anthracene and its many important derivative colors, at the head of which naturally stands alizarin. It is true that the preparation of commercial anthracene is by no means as easy as the separation and refining of most coal-tar crudes. It is a branch to which special attention was devoted in England before the war, and anthracene was the one crude material for which German color firms depended to quite an extent upon a foreign source.

There are, however, no inherent difficulties in this connection which cannot be overcome by persistent and intelligent effort. The raw material for the production of anthracene we now have in abundance, and it is earnestly to be hoped that the output of the hydrocarbon will soon assume such adequate dimensions that the manufacture of alizarin and a large group of allied colors may be promptly undertaken.

In this connection we reproduce from "The Dyer and Calico Printer" a valuable study on the subject, which appeared originally in "La Revue des Produits Chimiques":

Anthracene was discovered in 1832 by Dumas and Laurent in the oils obtained by the distillation of coal tar, and anthraquinone in 1840 by Laurent through the action of nitric acid on anthracene. The technical importance of these products dates from the synthesis of alizarin in 1868 and the development of the manufacture of coloring matters derived from anthraquinone. These are of remarkable fastness.

England was at one time the great producer of anthracene as also of all other products derived from coal tar. Thus, in 1880, the German color works transformed into dyestuffs about 1,400 metric tons of pure anthracene, of which only 200 tons were produced in Germany, the rest coming from England.

Before the war, it is estimated that the German works annually consumed more than 6,000 tons of pure anthracene, of which 5,000 tons were produced in the country. The rest, 1,286 tons in 1913, was imported chiefly from England and a smaller part from France. The mines at Lens, as a matter of fact, were anthracene producers. Their output in 1907 was 1,444 tons of crude anthracene. The German importation rose in the same year to 2,418 tons of crude anthracene, valued at 257,000 marks.

It must be added that Germany possessed almost a monopoly of the colors derived from anthracene. Outside of that country the British Alizarin Company alone produced alizarin and some colors made from it. We do not know the extent of this production, but do not think that it was more than a tenth of the German production. It would correspond therefore to about 600 tons of pure anthracene. This amounted to about 7,000 tons of pure anthracene. As the price of the colors made from it was at least 6 francs per kilo, their value was at least 40.000,000 francs. As the anthracene was hardly worth more than three to four millions, the plus value resulting from the transformation of the hydrocarbon into coloring matters is very important.

To cover the French consumption it is estimated that approximately 300 tons of pure anthracene were needed. Anthracene itself has no industrial uses, it is always transformed into anthraquinone. As a rule, the coal-tar distillers isolate the anthracene, bring it to a certain degree of purity and then send it on to the color works, where it is refined and transformed into anthraquinone.

Anthracene Manufacture.

Anthracene is isolated from the anthracene oils, which, in the distillation of coal tar, pass over between 280° and 400° C. It has an average specific gravity of 1.1. These oils form 16 to 18 per cent of the weight of coal tar, and contain from 2½ to 3½ per cent of anthracene. This is equivalent to an average content of .6 per cent of anthracene in coal tar. This content is influenced by its origin, according to whether the coal tar has been obtained in gas retorts or in coke ovens.

The figures show that very large quantities of material have to be manipulated in order to obtain a relatively small yield. The work is not without danger. Acridine contained in the anthracene oils causes cutaneous eruption and inflammation of the eyelids. All contact with the substances in the course of manufacture must therefore be avoided, and the plant should be provided with mechanical means to this end.

The anthracene oils, still warm, are left to crystallize in becks, and crude anthracene of a greenish color separates out on cooling, in the proportion of 6 to 10 per cent of the weight of the oil. By draining, filtration, or centrifuging this is separated. It contains from 12 to 22 per cent of pure anthracene. It is concentrated by crystallization in solvent naphthas, boiling from 170° to 200° C. Solution is effected in a horizontal boiler with an agitator and a double jacket serving for the circulation of steam.

The solution thus obtained is forced by compressed air into a vertical boiler with an agitator, and provided with a double jacket in which cold water circulates. It is cooled to 40° C., then filtered in a filter heated by hot water. The solid residue is centrifuged or pressed in a hydraulic press.

On cooling the warm solvent from the filter a less pure anthracene separates out, and this can be worked up in a new batch. The naphtha is recovered by distillation. Instead of this solvent, naphthalene oil obtained in the crystallization of naphthalene may advantageously be employed.

By this treatment a product containing 42 to 48 per cent of pure anthracene is obtained. Coal tar from the coke ovens furnishes the 42 per cent anthracene, that from the gas retorts averages about 47 per cent. At the same time, it must be noted that to obtain as pure an anthracene as possible it is important to choose very carefully the best fraction of the anthracene oils for the purpose, and this is governed by the origin of the coal tar and its composition.

The oils separated from the anthracene, which still contain some of it in solution, are usually added to creosote oil, and serve for the impregnation of wood, and for enriching coal-gas. Their composition is very complex. They contain phenols, methyl-naphthalenes, acenaphthene, phenanthrene, chrysene, diphenyl, carbazole, and other coal-tar derivatives which are held in solution.

The anthracene obtained, according to this process, is the industrial product. There were formerly also 22 to 30 per cent anthracenes. The 40 to 50 per cent product is now the only one on the market.

Anthracene is tested by Luck's method. It is oxidized with chromic acid in glacial acetic acid solution, and the anthraquinone formed is weighed after purification with dilute alkali and fuming acid.

In addition to anthracene, the commercial product contains notable proportions of acenaphthene, fluorene, phenanthrene, and carbazole, and smaller quantities of methyl-anthracene; pyrene, chrysene, acridine, diphenylene oxide, and paraffins.

Carbazole has acquired a commercial value during the last few years for the preparation of the vat colors, and it therefore is extracted by appropriate methods.

It is to be noted that the presence of methyl-anthracene, except in traces, spoils the shade of the alizarins. Also the content of paraffins may render the product unsalable. These compounds, however, are not found in undesirable quantities, except when the product has been obtained from coal distilled in gas retorts.

This impurity is easy to detect. On sulfonation with sulfuric acid of 66° Bé. on the water bath the aromatic compounds become soluble in water. The paraffins are not attacked and separate on diluting the liquid.

Purification and Concentration.

The 40 to 50 per cent commercial product is not employed in this state, although it was used at the commencement of the artificial alizarin industry. It is brought to 95 per cent by concentration.

This is usually effected by means of solvents in which the anthracene is less soluble than the substances which accompany it. Pyridine and acetone, out of many solvents which have been proposed, have been found the most suitable. The use of pyridine is claimed in a German patent. The operation takes place in a jacketted boiler furnished with an agitator. Compressed air is used for introducing liquids. About 3,000 kilos of anthracene is put into the boiler, then 5,000 litres of crude pyridine. The solvent is stored in enclosed reservoirs, built outside the works, in order to diminish the dangers of fire. If they are high enough the pyridine enters by gravity, otherwise it is forced in by compressed air. The cover is then placed on the boiler and the contents are heated to 100° C. This temperature is kept up for two hours, the agitator being kept going all the time. Steam is then shut off, and under continual stirring, the contents are cooled by running cold water through the jacket. The contents of the boiler are then run into an enclosed filter, in which the crystallized anthracene is separated from the pyridine mother liquor.

The anthracene remaining on the filter is treated again with 5,000 litres of freshly distilled pyridine in the same way. The pyridine running from the filter after this second treatment, which is relatively pure, serves for the first process. It is then recovered by distillation with superheated steam. A residue remains, which is run out while it is still liquid, and this solidifies on cooling. From 3,000 kilos of anthracene this residue amounts to 1,600 to 1,800 kilos.

The rectified anthracene still contains at least 25 to 30 per cent of pyridine, which is removed and recovered by a special process. The pyridine vapors are absorbed by sulfuric acid in a scrubbing tower, and when the acid is sufficiently saturated the pyridine is separated out with soda.

Crude acetone is also used, according to Bayer's patent. The choice of solvent depends largely on its price, and also on the greater or less facility of recovery. As relatively large quantities of the products have to be treated to obtain a rather low yield, the loss of solvent is necessarily high. It is estimated at about 10 per cent.

Instead of treating with a solvent to eliminate the impurities of the anthracene, chemical reactions can be used to separate the carbazole in the form of its potassium derivatives. A number of patents have been taken out to this end. This particular process has become important, as not only the anthracene, but the carbazole is recovered, and this latter product has become important for the synthesis of various vat colors.

The anthracene is finally brought to as finely divided a state as possible by sublimation with superheated steam. If this operation is well conducted the loss should not be more than 2 or 3 per cent.

Anthracene in the pure state forms white fluorescent scales. It melts at 213° C. and distils at 360°. It is but slightly soluble in the majority of solvents. It forms a picrate obtained as red crystals, fusible at 138° C.

It is interesting to note that absolutely pure anthracene is solely a laboratory product, whereas benzene and naphthalene are put on the market in a remarkably pure state.

Some Sources of Benzene and Toluene for High Explosives.

By T. F. E. Rhead.

[The following paper was read at the annual meeting of the Society of Chemical Industry, held July 18, at Birmingham. There is much of interest in it for American readers, as prospectively the demand for the two hydrocarbons in question may be notably increased in our own country during the coming months.—Ed.]

The preparation of synthetic phenol, and its subsequent nitration to picric acid, which has been successfully worked out on a commercial scale during the war, caused the great demand for benzene as the starting point of this process. The phenol used previously was obtained from coal tar, but synthetic phenol, being much purer, is far more satisfactory.

The trinitro derivative of toluene, T.N.T., was little known in this country three years ago, but the comparative safety with which it can be manufactured and handled, and its excellent explosive properties, caused an urgent demand for it, and consequently for the toluene from which to make it. The history of the Allies' success in producing this German explosive will, when written, be one of the most interesting romances of chemical industry.

The value of benzene and toluene for producing high explosives depends on their purity. Benzene is fairly easy to purify because it freezes at 4° C., but such is not the case with toluene, which freezes only when cooled to —90° C. Particularly troublesome impurities in some brands of toluene are those paraffin hydrocarbons which are neither removed by sulphuric acid washing nor by fractional distillation; such impurities complicate the nitration process and make it more expensive. However, when the supply of toluene was unequal to the demand, both the pure and paraffinic varieties were used for making T.N.T.; but since the sources of the pure substance have themselves become sufficiently developed, the paraffinic product, and likewise the processes producing it, have apparently been less profitable.

The various sources of benzene and its homologue toluene can be classified as follows:

(1) Synthetic, catalytic, and electrical processes.

(2) Certain crude petroleums containing them in the uncombined state.

(3) The destructive distillation of coal.

(4) The thermal decomposition or "cracking" of petroleum oils.

The methods under group (1) do not appear to have advanced much beyond the experimental stage.

When the urgent demand for toluene and then benzene had to be met, the Ministry of Munitions took the logical course of increasing the supply from the existing sources, and then of investigating and encouraging possible new sources.

The gas and tar from coke-oven recovery plants and a small proportion of gasworks tar supplied us with all the benzene and toluene we required prior to the war, and much was sent to Germany in part payment for the German recovery plants set up in this country. A large and little-known field of supply was town's gas, which often contains 30 to 40 times the amount found in the tar.

In the years immediately preceding the war the high price of petrol had focussed attention on benzol as a possible substitute, and several people had advocated washing this body out of town's gas.

Doherty, an American engineer, had urged the possibility in this country of recovering 2½ gallons per ton of coal carbonized for gas manufacture. However, the antiquated illuminating power standard prevented this procedure. The war demand put a new aspect on the problem, and a large and increasing proportion of town's gas is now being washed for these valuable products.

It became a matter of much import to know which system of carbonization gave the best yield, and although it is impossible to lay one's hands on reliable comparative data, the order of importance is, roughly: Horizontals, inclined, coke-ovens, intermittent verticals, and continuous verticals.

One great difficulty in solving this and allied problems has been the lack of a rapid, simple, and reliable test for the benzol content of a gas, and there is still much room for improvement in this test. It was early discovered that the benzol content of gas from continuous verticals was poor and high in paraffin content, and consequently not profitable to wash.

Many experimenters, encouraged by the Ministry of Munitions, worked on processes which were intended to increase the benzol content of coal gas. Experiments were carried out at the Birmingham Gas Works by Mr. E. W. Smith on the effect of carbonizing along with the coal such substances as coal-tar pitch, Mond gas pitch, petroleum residue, and bitumen in horizontal gas retorts.

The coal-gas pitch—a high-temperature product—does not give much increase in benzene and toluene, being already severely cracked, but the other three do materially increase the benzene and toluene content.. However, as only a small percentage can be carbonized at a time, it is not profitable to work the process for benzene hydrocarbon production.

Rollason, Stevenson, and others have tried the effect of carbonizing the coal along with lime or limestone, and claim that the latter acts catalytically and increases the yield of benzene, but further data are required to substantiate this claim. Experiments have also been carried out in passing inert gases and steam through gas retorts during carbonizing, in the hope of increasing the benzene yield by preventing its being thermally destroyed after formation, but little information is to hand as to the value of this method.

The various low-temperature systems of carbonization, introduced by the Coalite Co.—using a temperature of 400°— —500° C.,—produce no benzene, etc., but in the new coalite process employing a temperature of 650° C., a yield of 1.5 to 2.0 gallons of benzol per ton of coal carbonized is claimed.

It has long been known that various oils, especially those in crude petroleums, when subjected to the right conditions of temperature and pressure, break down or polymerise and yield a certain proportion of benzene and its homologues, the amount of which varies with the composition of the oil.

The mode of formation of benzene, etc., during the cracking of petroleum oils is parallel to that of its formation from the cracking of the primary decomposition products of coal. These latter contain many compounds found in petroleums, such as naphthenes, paraffin hydrocarbons, olefines, etc., and since it is far easier to separate petroleums into simple groups of compounds than is the case with coal, a systematic study of the thermal decomposition products of petroleum oil fractions should throw much valuable light on the mechanism of coal carbonization.

In Russia it has long been the practice to crack petroleum oils to obtain benzene and other aromatics for the dye and explosive industries and the shortage of coalfields made such an industry of vital economic importance. Moreover, Russian petroleums, being rich in naphthenes, lend themselves admirably to benzene formation. There is little doubt that this industry, founded by the Russian chemists, led by Nikiforoff, has received a great impetus from the needs of the war.

The first systematic work in the modern era, on producing aromatic hydrocarbons from petroleum, was carried out by Rittman, but the large-scale installation put down at Pittsburgh as a result of his experiments has been unable to compete with other sources of benzene and toluene owing to the small yield and poor quality of the products.

American chemists are working out the mechanism of oil cracking in a very careful manner, and much valuable work has already been done on the effect of temperature, time, contact, pressure, nature of the original oil, etc., by Rittman, Egloff, Moore, Twomney, and others.

The manufacture of carburetted water gas is essentially an oil-cracking process, and the evidence so far available goes to show that a good quality of benzene and toluene can be obtained by washing the gas from this process. In the early days of the war this source was unjustly ignored, owing to the lack of a good test for the benzol contents of a gas. The shortage of gas oil supplies has considerably handicapped this source in England, but it affords vast possibilities in America, the home of carburetted water-gas plants.

Some tests made at the Birmingham Gas Works showed that, of the oil cracked in this process, 3.27 per cent. appeared as benzene and about 2 per cent. as toluene, and the products were not seriously contaminated with paraffin hydrocarbons.

Egloff, experimenting with a Lowe carburetted water gas plant, obtained per 1,000 cu. ft. of gas, 0.07 gal. of benzene, 0.06 gal. of toluene, and 0.01 gal. of xylene. On this basis he estimates that the carburetted water gas manufactured in America, if washed, would yield annually 8,689,000 gal. of benzene, 7,448,000 gal. of toluene, and 1,241,300 gal. of xylene.

The Recovery of Toluene from Illuminating Gas.

The question of increasing the national supply of toluene by recovering the relatively small amount present in the illuminating gas of our cities is under active discussion. At a special meeting of the American Gas Institute, held in New York City in June, Mr. W. H. Gartley presented the essential factors of the problem very fully, as follows:

It has developed in the last few weeks that there are demands for trinitrotoluol for which no substitute can be accepted. Picrates made from the benzols are recognized for certain grades and kinds of high explosive work, and in one form or another will be used to a very large extent, but the urgent demand at the present day would appear to be for trinitrotoluol.

Increase Must Come from Gas Companies.

If there is to be any increase in the amount of trinitrotoluol made it must come from the toluol produced by the gas companies. All of the steel companies, with but one or two exceptions, that are now operating coke-oven plants have in operation light oil recovery plants in connection therewith and are producing therefrom pure toluol so that there is no use in looking to the steel companies or to the coke oven plants for any large additional amount of toluol in the immediate future. It is true that the coke-oven plants now under consideration and building will, within eight months to a year,—depending on the speed with which these coke-oven plants can be erected and put into operation,—increase the output of toluol to some 14,000,000 gal. per year, but at the present time any increase above the 10,000,000 or 11,000,000 gal. must come from the gas manufactured from gas companies, with possibly some small additional amount that can be had from natural gas by certain chemical processes. I would say, without betraying any confidence, that there is every prospect that there will be needed additional amounts of toluol. The Government officials have not said this; but we believe that beyond any reasonable doubt there is going to come to the gas companies a sudden and loud call for the recovery of toluol surely, and probably the toluol and benzol from their gas, and it is not unlikely that every gas company in cities of 75,000 inhabitants and over will have to give this matter immediate attention.

Therefore, from the standpoint of the Government officials, the information of our committee is that the need of the military branches for the by-products of the gas works has not yet dawned sufficiently upon the minds of those men of the Government who are able to commit the Government to any line of action, to force them, in the tremendous press of other matters, to act on this one. Apparently the Munitions Board at this time is not yet sufficiently conversant with the needs of our Army and Navy and those of our Allies to see clearly the way out of the difficulty as to the method of getting more of these by-products.

Now as to the gas companies' position. The gas companies are, of course, waiting for some word from the Goverment before they can go ahead to begin to put in these recovery plants. Is it true that the Government wants more toluol and benzol? Are the other materials that are needed to be used with toluol in the manufacture of trinitrotoluol available in sufficient quantities for the manufacturers to use a large extra amount of toluol?

Installation of Plant an Important Item of Expense.

The installation of such recovery plants is going to be a very important item of expense, especially at this time when we believe we are on the crest of a wave of high prices for labor and material and the almost insuperable difficulties in the way of getting materials.

Again, there are some of the largest companies where the most toluol can be obtained per dollar invested or in a given time, that are prevented from going into the business on account of the candle power standards set by the public service commissions or by contract. It will be necessary, before such companies can start on this to have these high candle power standards withdrawn, and that these companies be allowed to take out the toluol and benzol and leave a good satisfactory gas for the consumers.

Effect of Recovery on Gas.

What effect will the recovery of toluol and benzol from the gas have upon the gas sent out to the consumers? Personally, it seems to me very clear that the questions of a large reduction in heat units, and the recovery of toluol from the gas, are very distinct. If it is desirable to get all the toluol that is practically possible from our gas, the maximum quantity can be obtained if the gas companies will use in the manufacture of water gas as much oil as they are using at the present time, since the production of toluol is a function of the amount of oil used. I am referring now to those works making a high candle power gas. It would not be necessary or desirable for those gas companies, if they were relieved of their candle power requirements and put on a heat unit basis as many of the other gas works are, to reduce the quantity of oil used so as to get down to the lower standard of heat units; that is, speaking as I am from the point of toluol recovery. In those companies that are now working to, say, 550 to 570 heat units, it might be possible, although at extra cost, to make up by the use of additional oil for the loss in heat units due to the benzol oils recovered and not put back, when they get started on toluol recovery.

The gas companies now find themselves in rather serious straits, and the question of an increase in their rates is one that must engage the attention of the authorities in a very short time. The increasing costs of labor and material have very much increased the cost of gas, and the companies generally may justly claim the right to increase their charges.

Relation to Rate Changes.

But the question of the recovery of toluol and the loss in the heat units and candle power caused thereby might be considered, under ordinary times, as a feature of the whole question of change in rates, but at the present time it should not be so considered, and in saying this I know that I am to some extent antagonizing the representatives of the Bureau of Standards with whom I have talked.

These representatives have said to me that if the toluol, or both the toluol and the benzol are recovered from the gas, either wholly or in part, there will be a reduction in the heat units and also a reduction in the candle power, and the consumer will get less for his money than he did before, and consequently this is an argument in favor of a reduction in rates to the consumer under these conditions.

My reply to this has been that the emergency will not permit of mixing this question with that of change of rates for those companies that are now making a high candle power gas; that the reduction of heat units, due to the recovery of toluol, would not be sufficient to lower the gas below a first-class heating value; that where this gas is made up of mixed coal and water gas, or water gas alone, it would still be possible in New York, Chicago, Brooklyn and Philadelphia to recover the toluol and leave a gas of as good heating value as is distributed to the consumers of the other gas companies in those states; and that the burning of the toluol and benzol now being sent out by those companies, which are obliged to use a large quantity of oil per thousand feet, is almost a crime in view of the pressing necessities, for high explosives, of our young men who are now going out to fight our battles. I believe that it will be necessary for the proper Government officials to take up with those authorities having jurisdiction over the larger gas companies now making high candle power gas, the question of at once relieving them of this necessity.

This of course must be done by careful consideration of the conditions surrounding each individual company and it will require in this capacity a representative of the Government who has intimate and particular knowledge of the gas companies' conditions, of the relations of the gas companies to the consumers, and in a general way all of the many questions that have hedged the gas companies in regards to their regulations and legal conditions.

Cost of Equipment Question to be Settled.

Now, outside of these large companies with high candle power requirements, there is nothing particular, as a rule, to prevent the gas companies at once starting in to recover their toluol upon notice from the Government to go ahead, except the question of cost of equipment and how the gas companies are to be reimbursed and provide for amortization of the plant in a very short time, say a year and a half to two years.

The cost of erection of these plants will because of the press of high prices at this time, be such that the companies will not get their money out of the plants within a year if toluol sells at $1.50 per gallon. The Government in this case should be willing to provide the money for the erection of these plants, or they should guarantee to the gas companies such a price for their toluol over such a period of time as will surely provide, with economic and careful work in the matter of toluol recovery, for amortization of the plant and those incidental expenses, such as reduction in volume, etc., that are contemporaneous with toluol recovery.

I hope that there will be a discussion here today of what is in the minds of the managers of gas companies regarding this question of toluol recovery. This will be useful in guiding the committee in its work. This committee has had several meetings and a number of things have been developed and a great deal of progress has been made in clearing up the situation for quick action. We have shown the Government that it must come to the gas companies for any excess toluol until the time when the steel companies can get ready to increase their production; that the gas companies can not act until the Government tells them to, and we are prepared to discuss, upon invitation, the procedure to be adopted in order to get this additional toluol. A survey of the quantities of toluol that will be required for ourselves and our Allies has been made in Washington and the facts obtained from that survey make us believe that the Government will have to strain every effort to get all the toluol that can be obtained, at least from the larger companies.

Replying to a question as to whether the committee had come to any definite conclusion as to the smallest plant it thinks could be operated in the production of toluol, Mr. Gartley explained further:

That is a question which can be determined very largely by the amount of toluol the Government will need. Of course, there is also the question of the building of the plant to do the nitration and the securing of the nitric acid and the sulphuric acid. At the present time the Government is seriously in need of more toluol than is at present produced, and that production is now about 10,000,000 gal. yearly.

There would be provided by all companies in cities of over 75,000 inhabitants, eliminating those now taking out toluol and those with natural gas, something like 3,500,000 gal. additional. Whether this is sufficient to give the Government all that is needed has not yet been officially stated, and it probably never will be stated because it is based on certain conditions and the evidence is very strong that there will be a still greater demand than is now figured on as being necessary to prepare for immediately. It is quite conceivable that the gas companies in cities of as low as 40,000 inhabitants may be called upon to recover their light oils, and the collection may still be made more general.

If you have 570 heat unit gas, you will not get as much toluol per thousand feet of gas as those companies manufacturing a high candle power because you will not use as much oil. Assuming a recovery of 0.05 of a gallon of pure toluol per thousand feet of gas—and it may be that this is a little high for the average—I have said that towns of 75,000 inhabitants will recover 3,500,000 gal. of pure toluol. The Government is not now, I think, figuring ahead more than six months, and you can readily see that there is so much to be done at once that six months ahead is a long way from now, and the main question now is to get toluol from the gas companies and be reinforced later by the additional quantity that will come from the steel companies.

Mr. Ramsburg thinks that 3,000,000 gal. will be produced by the new steel plant being erected. The future of the toluol business, after the war, of course is not at all encouraging. The only use that you can have for it that is known now is its substitution for gasoline as a motor fuel, and in dyes and a few medicines.

In 1913 there were only 750,000 gal. of toluol produced in the country, so when you come to making 17,000,000 gal. and knowing what to do with it after the war is over, I think the steel companies can have that business if they want it.

The benzol production is liable to be embarrassing. In order to get out this toluol so much benzol is also taken out that the market is filled with benzol, so that the price can not stay up.

There has been an enormous increase in the coke-oven business in Germany. They have succeeded in getting nitrogen out of the air to make their nitric acid, and are using and have used trinitrotoluol right straight along. In England and in France very small works are undertaking the recovery of toluol. They were in terrific haste to get something. You will remember how, under the pressure of their demands, the prices of toluol increased about twenty-five times its former value in this country, and their idea was to get it out of all the small works. But they made one mistake.

Mr. W. H. Fulweiler, upon request, furnished the following explanation regarding methods of recovery in England:

In the mad haste the English people had to fortify with high explosives, they adopted what is known as a "C" process, which was the suggestion of Charles Carpenter. He said any old works can rig up a tar scrubber, and that was the most available means to get the tar out of their gas. They simply brought the coal tar into contact with the gas and extracted some 60 per cent. of the toluol, and the tar was sold to the tar distillers. But even with the introduction of the mineral apparatus, there was the serious handicap that they were handling a five-rail fence in order to catch a sparrow. The amount of toluol secured was very small.

Furthermore, the tar distillers over there, according to the gas literature, did not supply it on any arrangement like fifty-fifty, on the increased production of toluol. Furthermore, it was difficult to arrive at any correct referee method of determining how much they had enriched their gas. So it did not turn out to be a satisfactory process. All of the larger plants then began to turn almost immediately to oil instead of tar. They used practically the same scrubbing apparatus, and then they steamed their oils, and this increased the efficiency of their extraction. From that they have developed into flowing live steam into this oil with which the gas has been scrubbed, and they can in that way get a higher oil extraction and recover all light oils.

Mr. Gartley amplified Mr. Fulweiler's explanation by the following statement: I think the method we should use is to wash the light oil out of the gas by the use of a wash oil, and select as a wash oil one from which the light oil can be readily separated. The process is to wash the light oil out of the gas; then separate the light oil from the wash oil; then distill the separated light oil so as to get one fraction particularly rich in benzol, another rich in toluol, and leave the residue in the still, unless you want to go one step further and separate also the light naphthas.

The next step, then, would be the refining of these crude benzols and crude toluols into pure products. This can be done at the gas works but it is not an essential part of the gas works' plant, since these crude benzols and crude toluols can be shipped to other places for refining, provided transportation facilities are available. We must keep in mind the great scarcity of tank cars, barges and steel drums and the high prices for those commodities if new ones are purchased.

If there is no demand for your benzol, of course it must be immediately put back in your gas, leaving only the toluol fraction to be treated. You will not be able, probably, to figure on taking all of the toluol, benzol and solvent naphtha out of the gas; with some water gas if you did, it would bring the candle power down to three or five candles, and of course this is too low to send out. So you will have to be satisfied in taking out the material which when distilled and washed with acid will net 0.04 to 0.05 of a gallon of pure toluol per thousand feet of gas, depending on the quantity of oil used in making the gas. The amount of light oil recovered from the gas will be determined by the amount of wash oil that each thousand feet is exposed to in the wash oil scrubber. It will be possible to take out 0.04 to 0.05 of a gallon of C. P. toluol with the use of six gallons of wash oil for each thousand feet of gas.

To get all of it you might have to use 20 gal., and this of course would mean a large increase in the size of stills necessary to handle this large quantity of wash oil. Therefore, it is advisable to get a wash oil that is avid for the light oils in the gas and which will readily give up this light oil again under proper heat treatment in stills, since by this method you can reduce the size of the plant needed. It is very unsafe to make any attempt, based on experience of three or four years ago, to prophesy what it will cost to put up an apparatus that will simply recover the light oil from the wash oil, and divide the light oil so separated into crude benzol, toluol and naphtha fractions. In a city of 75,000 inhabitants it would appear that it would be unsafe to say that the cost of a plant for the recovery of toluol could be covered for less than $2.00 per gallon of C. P. toluol for a period of two years.

It is desirable that the selection of the apparatus to be used for toluol recovery be as cheap as possible, yet it should have the main consideration of reclaiming as much toluol as possible from the gas consistent with leaving a good serviceable gas for the consumer, and producing the toluol in such a way as to be available at once for the manufacture of munitions.

Equipment Needed.

It does not require much special apparatus. The main thing is to get hold of some steel. I know that this is not easy to get new, but I have in mind taking some steel containers that you may be able to pick out from your older material around your works, and if you have nothing of that kind that can be taken down you want to think a long while before you think of getting sheet steel on any new orders that you will now put in. Perhaps there may be some relief in this direction when the Government finds the absolute necessity of getting this toluol out. The other necessities are a few castings which you should be able to get because they are not large, and if you can get these castings and the necessary sheet steel. not much more is required, and you might poke around your works for the balance. Of course, if you want to build a handsome plant for show, it will take you sometime to get it and the war will probably be over when you are ready to produce toluol.

The German Coal-tar and Explosive Industries.

An understanding has been arrived at between the works of the big chemical industry, the so-called "aniline" concerns, and the "explosive group," and indirectly also with the "powder group," which latter works in connection with the explosives group. The new arrangement may be looked upon as settled, even if all the documents have not yet been actually signed. The aniline works, from the stoppage of their export trade and the dearth of raw materials, have been compelled to curtail their regular peace manufacture, and instead go in for the production of materials used in the explosives industry and of actual explosives. It is this increased production of explosives, etc., which has enabled Germany to carry on the war as she has, and has even resulted in a surplus, and this, again, is due more especially to the vast increase in the atmospheric nitrogen industry. As long as the war, with its immense munition requirements, goes on, this increased production will not be attended by any drawbacks. The new arrangement is only intended to come into operation after the war. Its purpose is to secure and fix the production of the respective groups, which at present is very much alike, and to lay down mutual limitations of the manufacture. The individual groups will maintain their complete independence and entire freedom within the allotted domain, and will consequently also have free hands altogether as regards their price policy.—*Engineering.*

Estimation of Benzol in Gas.

According to the *Gas World,* Neubeck's method of freezing out the benzol of illuminating gas, for the purpose of analytical estimation, gives good results in the laboratory of the Zürich gas works. Solid carbon dioxide is used and a uniform temperature of 79° C. is maintained. The condensate is free from oily matter but its very low specific gravity, 0.852 at 17° C., indicates the presence of lighter components recovered, also, from the gas.

Coal-Tar Crudes in Australia.

Little effort has been made hitherto to secure benzene and toluene from the coal-tar of Australian gas works. Under the stimulus of the present heavy demand for the two hydrocarbons in the manufacture of munitions, the Defense Department of the Australian Government has decided to erect the necessary plant for refining crude benzol, and to secure all available supplies of the latter from the gas companies of the commonwealth.

The British Supply of Coal-Tar.

Early in the year, the British Controller of Coal Mines appealed to the gas industry to economize as far as possible in the consumption of coal, in the interest of all fuel users, urging the substitution of water gas wherever practicable. This policy is now reversed, as the Minister of Munitions finds it necessary to secure the maximum output of coal-tar by products. The most recent instructions are to utilize the distillation plants of all gas works to the fullest extent before manufacturing water gas, carburetted or uncarburetted. The effort is made to recover as much of benzene, toluene and phenol as possible.

COAL-TAR INTERMEDIATES

Sulfonating Kettles.

The sulfonic acids, in almost bewildering variety, play such a dominant rôle in the manufacture of synthetic colors, that all pertaining to improvements in the processes of their industrial production possesses a constantly increasing economic value.

In *Metallurgical and Chemical Engineering* for August 15, 1917, Mr. Frederick Pope, who has devoted much attention to the technique of this branch, contributes a valuable study, profusely illustrated, on the fundamental factor of the manufacture, the kettle or "sulfonator." From the exhaustive study we quote the following:

Sulfonating kettles are made of cast metal, for instance, cast iron or various acid resisting metals such as Duriron, Tantiron, Corrosiron, Buflokast, etc., the ratio of depth to diameter and shape of bottom varying widely according to the service required of the kettle. They are ordinarily discharged either through the bottom or through a permanent or temporary tube inserted through the top, in which case air pressure is used to empty the kettle.

A frequently used type of sulfonating kettle is made of cast iron. The jacket may be either cast iron, or more often, boiler plate. Such a kettle is useful for such sulfonations as require either no external supply of heat, or a supply of heat at a low temperature.

Usually the source of heat is low pressure steam in the jacket, the steam being admitted through openings around the top of the jacket, and the condensation drawn off through an opening at the bottom.

This type of jacket is used when the source of heat is hot water, or when cooling water is used to control the temperature within the kettle.

When the kettle is heated by low pressure steam, a space of 1 to 2 in. between the outside of the kettle and the inside of the jacket is sufficient. but when hot water is used for heating or cold water for cooling, the space should be at least 4 in. These figures are for medium sized kettles, 4 to 5 ft. in diameter. When either hot or cold water is used, care must be taken that it is introduced at a number of points, and drawn from a number of points to prevent hot or cold streaks in the jacket.

Steam jackets of this sort carefully designed and well built may be used for temperatures up to 130° C. The jacket should be carefully insulated with asbestos or other non-conducting covering.

An example of a kettle of this sort is the one used in the sulfonation of benzol to benzol-sulfonic acid, which is heated to a point between 80° and 110° C., depending upon the method used, and is equipped so that water may be admitted into the jacket for cooling in case of overheating.

When a higher temperature than 110° C is desired, we face a more difficult problem. If we use steam as the source of heat, higher pressures are necessary, and we have the awkward problem of cylinders of large diameter subject to collapsing pressure from the outside.

A number of methods have been devised for solving this problem. Superheated water is successfully used abroad in place of high-pressure steam. In constructing a kettle for high pressure steam, coils of wrought iron pipe are placed in the mold for the kettle, and cast iron is poured around them. It is reported that this construction is successful abroad. According to available data it has never been very successful in this country, the difficulty being the difference of coefficients of expansion between wrought iron and cast iron. It presents a very attractive method of heating if it can be worked out.

In another method of construction for high pressure steam, the jacket and inner shell are made of boiler plate, into which a lining of cast iron is poured.

Another method of getting high temperatures is to use superheated steam, the steam being at a low pressure. The objection to this method is the fact that one encounters innumerable well-known mechanical difficulties. The chief objection to superheated steam, besides these mechanical difficulties, is the fact that the more highly steam is superheated, the nearer it approaches a gas, and the less becomes its weight per cubic foot. Both of these lessen its value as a medium of carrying heat.

A perfectly obvious way of obtaining high temperatures in sulfonating kettles is to discard entirely the jacket and to heat the kettle directly, using preferably gas or oil for fuel, or to heat the kettle in a current of hot gas coming through a checkerwork, the checkerwork tending to give even temperatures.

Another way is to surround the kettle with a steel jacket, forming an air bath. This method has been successfully used, but the thermal efficiency is not high.

The last method for heating a kettle to a high temperature is by the use of some circulating medium, for instance, oil. In such a case we use a kettle similar to that adapted for hot water heating, the oil entering a number of places in the bottom, and leaving through a number of openings spaced around the top. Such a system requires, in addition to the kettle, a heating coil, a circulating pump, an expansion tank, and a reflux condenser. The expansion tank should be equipped with a steam-heating coil to heat the oil before circulation is attempted. The first time the oil is used, the temperature should be raised gradually, as even the best circulating oil contains some water, which must be driven off before this system will work smoothly.

Temperatures up to 150° C. may be maintained with the mineral oils available without serious deterioration of the oil. If it is desired to maintain a higher temperature, the oil-circulating system should be provided with a reflux condenser to return to circulation anything that might be driven off. When the system is equipped with reflux condenser, temperatures up to 300° may be maintained.

A standard form of superheater re-arranged so that all the pipes are in series instead of some of them in parallel makes an excellent oil heater. The heater is preferably fired with oil or gas on account of the ease in regulation. This system should be equipped with a recording thermometer. In a well-designed oil-heating system, it is possible even when running a number of kettles from one heater to maintain the temperature within one or two degrees.

A sulfonating kettle is ordinarily equipped with a thermometer tube extending well into the liquid. It is always desirable to use a recording thermometer in connection with a kettle.

A sulfonating kettle must always be provided with a cover to prevent loss of acid through evaporation or the weakening of the acid by abstracting water from the air. The cover may be of cast iron or boiler plate. The joint between the kettle and the cover is usually made either of lead or asbestos, although in some cases the cover is simply bolted to the kettle. The cover should have the following openings: A manhole as large as possible up to 14 in. by 15 in. diameter; an opening to admit sulfuric acid; in some cases a pipe connection to admit liquids, as for instance in a phenol plant, benzol, while in other cases, in making b-naphthol for example, the material to be sulfonated is charged through the manhole. In some instances, it is desirable to have an opening for a pressure gauge or other form of manometer. If the kettle has not a bottom discharge, there is either an opening for inserting a temporary tube to the bottom or a permanent tube extending to the bottom, and an opening for compressed air for discharging the charge. It has been proposed to discharge the kettle through a hollow agitator shaft, but this is not recommended. There may be necessary an opening for the escape of fumes or for a condenser.

In the case of many reactions, often in the sulfonation of amino compounds, the reaction mass must be cooled in order to limit sulfonation. This cooling may be accomplished by either introducing water into the jacket if possible, or by having closed-end pipes of enameled or acid resisting iron extending into the mass, and running cooling water or brine through these pipes.

The apparatus must be designed to meet the requirements of the reagent used. Ordinary pig iron, which is generally employed, can not be used with fuming acid, since it is quickly corroded by the high temperatures, which are often maintained for hours, in such a way that gas accumulates in the pores of the iron (hydrogen, carbon dioxide, etc.) which may cause disintegration. Wrought iron is strongly corroded by fuming acid containing up to 25 per cent SO_3, at which strength it is again passive.

Various linings may be used. Enamel or lead applied directly to the inside of the kettle, or a chemise of nickel are used. The advantage of a nickel chemise is that when it is used up, it may be withdrawn and replaced by a new one.

Kettles have been built with horizontal stirring devices, but this is not desirable because of the difficulty in keeping the stuffing boxes tight when the shaft is in a bearing in contact with acids. It is also true that a horizontal stirring apparatus requires more power than a vertical one. A slanting stirring device gives uniformly good results, but for some undetermined reason is seldom used. The writer recommends it to the earnest consideration of users of sulfonating kettles.

Nearly all sulfonating kettles are provided with agitators of which there are a number of forms in use. The ordinary "U" type of agitator with the center line of the shaft coinciding with the center line of the kettle is a common type, and for many uses very successful. This type of agitator is also used with the center line of the shaft parallel to the center line of the kettle, but a little off center, which gives a better agitation.

Another type of agitator which is very useful for certain purposes consists of a number of "U" type agitators with breakers.

The propeller is largely used as an agitator in a number of different ways, and although it is undoubtedly the ideal agitator under certain conditions, it cannot be used indiscriminately. There is one correct speed for the propeller type of agitator, which depends upon the size and shape of the kettle, the size, form and pitch of the propeller, and the liquid in the kettle. A comparatively small variation from this speed will reduce greatly the efficiency of the agitating device. It follows that the propeller type is usually unsuitable in a sulfonating kettle in which the character of the liquid changes in the course of the reaction.

A single propeller is often used. A modification of this, considered by some to be an improvement, is to inclose the propeller in a tunnel.

Another arrangement favored by many is two propellers on the same shaft, one propeller throwing in one direction, and the other in the other. Often these propellers have varying pitches. An arrangement of this sort well thought of in England has two propellers working in different directions with different pitches, with side breakers on the inside of the kettle, the shaft carrying the propellers revolving rapidly (250 r.p.m.). In certain work, it is reported to have been very successful.

In the opinion of the writer the best arrangement of the propeller is either one or two propellers; in case two are used, with varying pitches, and throwing in opposite directions, the shaft carrying the propeller or propellers parallel with the center line of the kettle, but a certain distance off center.

There are a number of special types of agitators for particular service used in sulfonating kettles. For instance, there are kettles built in which the shaft carrying one agitator is hollow, another shaft extending through the hole in the shaft carries another agitator revolving in the opposite direction. There are scraper types of agitators for particular purposes. In fact, the desirable type of agitator must be chosen in each case, and can only be determined by experience and study.

In a bottom discharge kettle, the design of the bottom discharge must be carefully considered. Many makers design a sulfonating kettle in which the discharge pipe passes through a stuffing box in the outer jacket and is screwed into the sulfonating kettle. For some uses, this construction is applicable, but often the screw threads are attacked by the acid, the threads in the casting being attacked as well as the threads in the discharge pipe. When the threads in the kettle have been destroyed, troublesome repairs are necessary. It is much better to introduce a spool piece between the kettle and the jacket. The valve controlling the discharge can be bolted directly to this spool piece.

Another method is to make the discharge pipe of cast iron with a flange cast on either end. The discharge pipe is bolted to the sulfonating kettle, passing through a stuffing box in the jacket. In this case it is necessary that the stuffing box and gland be split.

There has been considerable interest of late in continuous sulfonation, a number of schemes having been devised for the purpose. A step in this direction is sulfonation in two stages, which has been very successful in at least one large works.

Explosions of Picric Acid.*

By T. Sington.

The process of making picric acid consists broadly in mixing carbolic acid with strong sulphuric acid, diluting this sulphonate with water and then running it slowly into nitric acid. The mixture is allowed to cool, when the crude picric acid crystallizes out and it is subsequently purified by re-crystallization. After thorough washing with water to remove all traces of free nitric and sulphuric acids, the material is whirled in a centrifuge to remove the bulk of the water. It is then removed to the drying shed where it is spread on glass steam-heated beds until all moisture is removed. The acid is then transferred in large open drums to the sifting room where it is ground, passed through a revolving screen, taken to the packing room, and packed in barrels of 100 pounds each. The large crystals which fail to pass through the sieve are reground in a crushing mill.

A suitable range of buildings for the manufacture of picric acid may consist of five buildings in which the wet processes of manufacture are carried out, and of four or more others in which the acid is dried, sifted, packed, and stored. These buildings ought to be separated from one another and from the "making" rooms by intervals of about 30 feet.

Explosions in picric acid factories are of rare occurence, but the destruction is then so thorough that there is considerable difficulty in tracing the cause. In opinions based on prolonged experience and on records extending over a long period of time, it has been considered that an explosion is impossible, provided the quantity of acid in any one building is limited to a moderate amount and that the acid is absolutely free from picrates. An entire factory may thus be regarded as constituting a fire risk rather than an explosion risk, and consequently no distances beyond those necessary to prevent the communication of fire are necessary. Brick walls have therefore been deemed sufficient to protect life, inasmuch as explosions of picric acid have always been preceded by a fire of some minutes' duration.

In the case of an explosion of picric acid two separate and distinct questions may present themselves for discussion: First, the means by which the heat necessary for ignition is produced, and, secondly, why an ignition may develop into an explosion, instead of merely resulting in a comparatively harmless combustion. One of the manufacturing processes through which the material passes is of a nature which in connection with explosives is never entirely free from risk—this is the operation of grinding the larger crystals of picric acid which have failed to pass through the screen. While picric acid is by no means easy to ignite, when it occurs ignition is most likely in the grinding mill. Thus, the operation of grinding *dry* acid occasionally gives rise to fires, which may not be followed by explosions and which are readily put out, but the possibility of explosion is always present.

That the mere process of grinding is not necessarily dangerous follows from the immunity experienced during the operation of drilling out the primer space in the solidified charge of filled shells by means of power-driven steel drills, a method which has been very generally employed without the slightest accident. It does not necessarily follow that because picric acid may be safely ground in an iron mill, that nails, stones and similar hard foreign bodies which may accidentally find their way into the powdered material, are equally harmless. In fact, many fires in picric acid factories have been traced, after careful examination, to the presence of a nail in a grinding machine. Foreign bodies may find their way into the hoppers of grinding machines in a variety of ways, but it is contrary to all experience that an explosion should follow ignition. Should this occur, it would be necessary to reconsider all previous conclusions, and even to modify to a very considerable extent the conditions of manufacture.

A picric acid explosion of exceptional violence, causing widespread destruction of property, occurred in one of the manufacturing towns of Great Britain many years ago. After an exhaustive inquiry it was established beyond all possibility of doubt that the explosion was due not to picric acid alone, but to the presence of considerable quantities of lead and strontium compounds, which under the influence of heat and in contract with the melted picric acid led to the formation of lead and strontium picrates, both of which, and more particularly the lead salt, are not only in themselves violently explosive, but are capable of detonating picric acid in contact with them. Another explosion of picric acid occurred after a fire had been raging for nearly ten minutes; it was said to have been due to the formation of picrate of lime from the mortar in the roof of one of the buildings.

Textbooks for many years stated, on the authority of chemists of the highest standing, that when suddenly heated, picric acid will explode, but the actual experience of manufacturers furnishes a very emphatic contradition to this statement, that pure picric acid when unconfined cannot be exploded by fire. Investigation of accidents such as the above also support this view, as do also the results of experiments instituted for the special purpose of clearing up this point. A case is recorded in which an iron vessel with a very small orifice and containing 25 lbs. of picric acid was placed in a reverberatory furnace, when the acid burned away without explosion.

It has been found quite possible to explode picric acid by a blow, but the blow must be one of considerable force, if the material is cold. In fact, all experience appears to prove, as surely as negative evidence can be said to prove anything, that it may be taken as a practical impossibility for picric acid to explode without giving sufficient warning by fire to enable anyone in the vicinity to escape, and moreover a fire in its initial stages can be extinguished by water without much difficulty.

---

* From *Metallurgical and Chemical Engineering, August 1, 1917.*

In the best planned picric acid factories the quantity of material which may be present in any one compartment is limited to 2000 pounds. When this limit is adhered to, and suitable sprinklers fitted up in every building liable to contain picric acid, the danger of a fire developing into an explosion is so slight as to be negligible. The process of dry grinding is also being discontinued, and some method of dealing with large crystals in a wet state substituted.

Manchester, England.

Conflagrations in Coal-Tar Chemical Plants.

During the past few months there have been so many fires in works devoted to the manufacture of coal-tar intermediates and colors, that the inherent causes have been a matter of much discussion. A recent issue of *The Journal of Commerce* contains the following extremely sensible review of the situation by Mr. E. O. Torbohm, a well-known insurance inspector:

"There is danger that several recent fires in plants engaged in the manufacture of intermediates for aniline dyes will lead underwriters to the mistaken conclusion that all chemical processes are alike dangerous. Analysis will show that most, if not all, of these fires are due in greater or less measure to war conditions, i.e., undue congestion or inadequate facilities, coupled with insufficiency of skilled help and a feverish desire for quantity of output rather than for quality. It may be further noted that only a certain class or type of these risks have burned or distinguished themselves explosively.

"American emancipation from dependence upon the German dye industry is now an old story. That our dependence in this respect was a purely economic one has been abundantly proven since the outbreak of the present world war. To the numerous eminently capable men efficiently qualified to lead in this emancipation have been added, however, a host of speculative jugglers, poorly equipped with the requisite ability, however well they may have succeeded in securing the necessary capital.

"Hastily renovated or reconstructed properties, illy adapted for the purpose, have been everywhere pressed into use, and machinery and equipment costing hundreds of thousands of dollars installed in mere shanties. When to these natural disadvantages are added the difficulty in securing uniformity in grade of raw material, and a sufficiency of capable workmen, the wonder is that so many low-grade plants remain intact.

"The built-for-the-purpose, efficiently equipped and adequately manned establishments are obviously not in the same category. Likewise the manufacture of staple crude and refined chemicals when rationally conducted should be free of any abnormal fire hazard. This is especially true of the manufacture of drugs and pharmaceutical chemicals. While the expected rewards have been equally as great, even greater, on certain items in this trade, the class or grade of men engaged in it seems to be of that high standard which makes for deliberation in action, as well as in thought. With few exceptions, there is as much difference between this class and the one responsible for the present chemical fire record as there is between a watchmaker and a boilermaker. Moral: Beware of the boilermaker."

Manufacture of Benzene-Sulfonic Acid.

A simplification in the manufacture of benzenesulfonic acid is proposed by the Compagnie des Produits Chimiques d'Alais et de la Camargues, Salindres France, (Br. Pat. 101,973 of 1916). Benzene vapor is passed through sulfuric acid, maintained at the favorable temperature. The excess of benzene, passing out from the sulfonator, carries along, in the form of steam, the water present in the acid and that liberated during sulfonation. This current of vapor is dehydrated before it is returned to the acid. It is claimed that the process allows the use of sulfuric acid of any degree of concentration, that all of the acid employed is effectively utilized, and that the resultant sulfonic acid is practically pure.

A New and Sensitive Indicator.

M. T. Bogert and G. Scatchard (J. A. C. S., 1916, 38, 1606) find that the monosodium salt of dinitrobenzoylene urea is a very sensitive indicator for hydrogen-ion concentrations between the limits of 6 and 8 on the Sörensen scale, changing from colorless to greenish yellow. It resembles p-nitrophenol most closely. This indicator is but slightly affected by neutral salts and proteins, not at all by chloroform, toluene or nitrous acid. It can be used in cold or boiling solutions, a sharp end point being obtained with ammonia and HCl. Its color fades very slightly in about a week, and it is not suited for titrating carbonates. It is believed to be superior to rosolic acid in preparing neutral ammonium citrate for fertilizer and soil analyses.

Dr. R. P. Rope, lately connected with the Mellon Institute at Pittsburgh and the General Coal Products Co., is now at St. Louis, engaged upon the construction of a phenol plant.

Dr. Allerton S. Cushman, president of the Institute of Industrial Research at Washington, is now a major in the Officers' Reserve Corps, and has been assigned special research work on the chemistry of high explosives, under the ordnance section.

ARTIFICIAL COLORS

A Series of New Ortho-Oxy-Azo Dyestuffs Containing Copper.

Dr. Berthold Wuth and Dr. Carl Jagerspacher, of Basel, Switzerland, assignors to the Society of Chemical Industry, of Basel, describe (Amer. Pat. 1,233,433, of July 17, 1917) an extensive new series of azo colors containing copper, derived from various ortho-oxy-azo dyestuffs prepared from polycyclic ring systems in which there is a CH_2 group susceptible of combination with a Siazo group.

Such polycyclic ring systems are:—
diketohydroinden,

$$C_6\,H_4<\substack{CO\\CO}>CH_2,$$

peri-naphthindanion,

$$C_6\,H_4<\substack{CO\\CO}>CH,$$

3-oxy-1-thionaphthen,

$$C_6\,H_4<\substack{S\\CO}>CH_2,$$

ketocumaran,

$$C_6\,H_4<\substack{O\\CO}>CH_2 \quad \text{and}$$

indoxyl,

$$C_6\,H_4<\substack{NH\\CO}>CH_2$$

The above, as well as their derivatives, can be transformed into soluble copper compounds, by treatment with copper salts, copper oxide or copper hydroxide, similar to those obtained at an earlier date, by the inventors, from simpler ortho-oxy-azo dyes (Amer. Appl. for Pat. 43,413, of Aug. 3, 1915).

The copper compounds, soluble in water, thus obtained, from which the copper cannot be precipitated by sodium carbonate, soda lye and ammonia, yield in an acid bath on animal fibers and leather, further on straw and wood-bast, valuable red, brown, violet-blue to black tints of good fastness to washing and to light. They are distinguished from the ortho-oxy-azo dyestuffs, employed as parent materials, by entirely different shades and by a better fastness. The new copper compounds dissolve in concentrated sulfuric acid to deep colored solutions and in water to intense colored solutions which do not change their coloration on the addition of sodium carbonate or of soda lye.

The preparation of these dyestuffs from ortho-diazo-phenol derivatives or ortho-diazo-naphthol derivates and peri-inaphthindandion, ketocumaran, indoxyl, etc., takes place in the usual way by combining the ortho-oxy-diazo compounds with the various components in an alkaline solution, as is illustrated by the following example:

Example 1: 24 parts of 1:2:4-amino-naphthol-sulfonic acid are diazotized in the customary manner and mixed with a soda alkaline solution of 20 parts peri-naphthindandion, dissolved in 14 parts of soda lye of 30 per cent. The combination being achieved, the dyestuffs is separated, pressed and dried. It dissolves in water to brown-red, and in concentrated sulfuric acid to blue solutions, and dyes wool in an acid bath violet-brown shades.

The preparation of the copper compounds of these ortho-oxy-azo dyestuffs is illustrated by the following examples:

Example 2: 24 parts of the dyestuff obtained, according to Example 1, from 1:2:4-diazo-naphthol-sulfonic acid and peri-naphthindandion, are dissolved in 1000 parts hot water at 80° C., and into the solution is poured a solution of 13 parts of copper sulfate in 50 parts water. The copper compound separates at once as a black precipitate. After neutralization of the freed sulfuric acid with sodium carbonate, the new copper compound is isolated by filtration, pressed and dried. It dyes wool in an acid bath brown-red shades, very fast to washing and to light.

Example 3: 21 parts of the dyestuff resulting from 1:2:4-diazo-naphthol-suffonic acid and oxythionaphthen, are dissolved in 700 parts water, and to this solution are added, at about 70° C., a solution of 13 parts copper sulfate in 50 parts water. The blue copper compound precipitates at once. After neutralization with sodium carbonate, the new copper compound is separated by filtration, pressed and dried. It yields on wool in an acid bath very pure violet-blue shades, fast to washing, alkali and light, while the ortho-oxy-azo dyestuff employed as parent material yields valueless rose-colored tints.

The tabular exhibit (*p. 260*) shows the variety of tints obtained from a few of the possible combinations employed with polycyclic compounds.

In a later patent (Amer. Pat. 1,234,994, of July 31, 1917) the same inventors describe a closely allied group of dyes, constituted by the copper compounds of the ortho-oxy-diazo dyestuffs derived from ortho-carboxylated benzoyl-acetic acid.

$$C_6\,H_4<\substack{COOH\\CO-CH_2-COOH}$$

The preparation of the heretofore unknown dyestuffs from ortho-diazo-phenol derivates or ortho-diazo-naphthol derivates and ortho-carboxylated benzoyl-acetic acid takes place in the usual way by combining the ortho-oxy-diazo compounds with the

Dyestuff resulting from—		Dyeing of the sodium salt from acid bath on wool.	Dyeing of the copper salt from acid bath on wool.
The diazo derivate of—	And—		
$C_6H_3(OH)(NH_2)SO_3H$ [1:2:4]	Diketohydroinden	Yellow-brown	Red-brown
$C_6H_3(OH)(NH_2)SO_3H$ [1:2:4]	Indoxyl	Red-brown	Violet
$C_6H_3(OH)(NH_2)SO_3H$ [1:2:4]	6-Methyl-ketocumaran	Yellow	Violet
$C_6H_3(OH)(NH_2)SO_3H$ [1:2:4]	Peri-naphthindandion	Yellow-orange	Red-brown
$C_6H_3(OH)(NH_2)SO_3H$ [1:2:4]	3-Oxy-1-thionaphthen	Red-brown	Red-violet
$C_6H_2(OH)(NH_2)(SO_3H)COOH$ [1:2:4:6]	Peri-naphthindandion	Red-orange	Yellow-brown
$C_6H_2(OH)(NH_2)(SO_3H)COOH$ [1:2:4:6]	Diketohydroinden	Orange	Red-brown
$C_6H_2(OH_2)(CH_3)SO_3H$ [1:2:4:6]	3-Oxy-1-thionaphthen	Red-brown	Violet
$C_{10}H_5(NH_2)(OH)SO_3H$ [1:2:4]	Diketohydroinden	Red-brown	Violet
$C_{10}H_5(NH_2)(OH)SO_3H$ [1:2:4]	Peri-naphthindandion	Violet-brown	Bordeaux
$C_{10}H_5(NH_2)(OH)SO_3H$ [1:2:4]	3-Oxy-1-thionaphthen	Roseate	Pure violet-blue
$C_{10}H_5(NH_2)(OH)SO_3H$ [1:2:4]	6-Methyl-ketocumaran	Red-brown	Blue
$C_{10}H_4(NH_2)(OH)(SO_3H)NO_2$ [1:2:4:5]	3-Oxy-1-thionaphthen	Roseate	Black-violet
$C_{10}H_4(OH)(NH_2)(NO_2)SO_3H$ [1:2:4:6]	3-Oxy-1-thionaphthen	Brown-violet	Violet-black

said component in an alkaline solution. It is illustrated by the following example:

Example: The diazo derivative of 20 parts of sulfo-amido-salicylic acid

$$C_6H_2(OH)(NH_2)(SO_3H)COOH\ [1:2:4:6]$$

is poured into a concentrated solution of 21 parts of ortho-carboxylated benzoyl-acetic acid in water made alkaline by sodium carbonate. The dyestuff separated after combination is isolated by filtration, pressed and dried. It dissolves in water to orange-yellow and in concentrated sulfuric acid to pure violet solutions. On adding copper salts to the aqueous solutions their orange-yellow coloration turns to blue. It dyes wool in an acid bath brown tints.

In order to transform this oxy-azo dyestuff into its new copper compound 23 parts of the dyestuff are dissolved in 1,000 parts water and to this solution are added, at about 70° C., a solution of 13 parts of copper sulfate in 50 parts of water. The blue copper compound precipitates at once. After neutralization of the free sulfuric acid with sodium carbonate, the copper compound is separated by filtration, pressed and dried. It dyes wool in an acid bath blue tints fast to washing and to light.

If in the foregoing example the diazo derivative of sulfo-amido-salicylic acid is replaced by chloro-amino-phenol, 4-2-1, the sodium salt of the resulting ortho-oxy-diazo dyestuff dyes wool in an acid bath gray brown tints, while the copper compound derived from this ortho-oxy-azo dyestuff dyes wool in an acid bath dark-blue tints.

Marden, Orth & Hastings Rechartered.

The firm of Marden, Orth & Hastings, Inc., prominent manufacturers of artificial and natural colors, New York City, has revoked its charter under the laws of Maine and incorporated under the laws of the State of New York. The working capital of the company is listed at $1,950,000. The incorporators are: M. S. Orth, A. F. Burnham and E. N. Perkins.

Du Pont Opens New England Sales Branch.

E. I. Du Pont De Nemours & Company announce the opening of their dyestuff sales department for New England, at Turk's Head Building, Providence, Rhode Island, with George M. Snow, manager.

Growth of the American Dyestuff Industry.

Since January, 1915, the Bureau of Foreign and Domestic Commerce has done all in its power to stimulate and encourage the expansion of the American dyestuff industry. Great pains have been taken to keep in touch with its growth and to be in a position to inform the public, and especially the consumers of dyes, of the rate and nature of the expansion.

On August 15, the daily *Commerce Reports* contained an admirable *résumé* on this subject, which we here reproduce in full:

In response to inquiries for more complete information on the domestic industry than that given in the article on dyestuff production in the United States, which appeared in *Commerce Reports* for May 14, 1917, the Bureau of Foreign and Domestic Commerce on June 6 sent forms to all manufacturers of dyestuffs known to the Bureau, requesting their co-operation in securing more accurate returns. Practically the whole industry responded, the exceptions being a few minor firms and those just beginning operations and not in a position to calculate their probable output. Of 103 forms filled in and returned, all but three show in detail the capital invested and the variety, monthly production, and occasionally the quality of product manufactured by each firm, with frequent notations indicating the lines of experimental research now being conducted with a view to further development. On the remaining three forms reasons were given why only partial information was available.

Notices received during the year state that 12 firms have gone out of business or discontinued the manufacture of dyestuffs. Ten others have been eliminated by consolidations or absorbed by holding companies. An increasing tendency is shown in the industry to an amalgamation of interests among certain plants making crudes and intermediates with others producing finished dyestuffs, which will probably result in a more extended variety of colors at a decreasing cost of production. Several instances are noted where two or more allied corporations have apparently pooled their interests to facilitate the manufacture and marketing of their products, while one recent amalgamation includes some of the largest plants in the country.

Many of these great corporations have branches in various cities of the United States, and a few have established agencies in Latin-American capitals and in London, Paris, and Shanghai.

Capital Invested.

The capital stock given on 90 forms aggregates $158,913,650. According to notices of very recent incorporations, 22 new enterprises have a total capital of $4,112,000, making the total investment in the industry $163,025,650, as far as actual figures are available. This amount does not include the capital invested in dyestuff production by 10 firms, some of which are just beginning operations, while others state that they are not incorporated and have no capital stock, but are amply financed, or are owned by a single individual. These plants will probably be in full operation by 1918 and add several million dollars capital to the dyestuff industry. Another difficulty encountered in computing the total capitalization is the fact that a number of firms which formerly manufactured only explosives or a general line of chemicals state that their dyestuffs are by-products of recent development and that it is impossible to draw a line of demarcation to determine just what portion of their capital is invested in color production. No effort has therefore been made to supply these missing figures. If full and accurate data were obtainable, it is believed that the recent estimate of $200,000,000 invested in the domestic dyestuff industry, published in one of the trade journals, would be too conservative.

Twenty-one of these corporations have invested from $1,000,000 to $21,000,000 each, and 40 others have a capital ranging from $100,000 to $800,000.

Estimated Output of 100 Plants.

From figures submitted by the manufacturers the following totals of monthly production for the current year have been compiled:

Firms making returns.	Products.	Pounds.
22	Crudes:	
	Benzol, toluol, and some xylol and phenol......	*1,240,350
	Benzol, toluol, xylol, cumol, natural and synthetic phenol, cresol, naphthalene, anthracene.......	6,181,600
40	Intermediates	10,420,600
46	Artificial colors	5,000,000
13	Vegetable dyestuffs and extracts (including some tanning extracts not stated separately).........	8,183,500

---

* Gallons.

The above returns were submitted voluntarily and are as nearly complete as can be obtained by correspondence. For general purposes, they are fairly representative of the industry as a whole, though faulty from a statistical standpoint since, as stated, no returns were received from several minor firms so recently established as to be unable or unwilling to go into details of product and output, but whose combined production for the remainder of the calendar year would constitute only a small percentage of the whole. In some instances the figures for benzol are in excess of the amount used in the production of synthetic phenol. In this connection, it may be interesting to compare the above with published estimates by a leading authority on the subject that out of an approximate benzol production for 1917 of 220,000,000 pounds only 37,000,000 pounds would be used for dyes; and that there is a present indicated consumption of 12,000,000 pounds of naphthalene per annum in the manufacture of intermediates.

As stated by some of the larger firms, it is, of course, difficult if not impossible to give the exact amount of each article produced month by month, as the production varies according to the market. The demand for certain colors remains constant, while others are discontinued and the intermediates required in their manufacture are diverted to other purposes. The industry is still in the experimental stage, many products being manufactured on a semi-commercial scale, with processes not fully developed and qualities not yet standardized. In the case of the larger groups of amalgamations, the proper co-ordination of multiple phases of manufacture is being slowly perfected. The limited capital and productive capacity of newer plants frequently limit their operations to the filling of actual orders without any attempt to carry their products in stock.

Intermediates.

In round numbers, the 40 estimates of the monthly output of manufacturers of intermediates range from 1,000 to 2,000,000 pounds each. The monthly production of three factories reaches seven figures, and that of 15 others is expressed in six figures. Some of the factories make only the intermediates required for their own consumption in producing finished colors, some manufacture in excess of their own needs, while the efforts of others are confined to a line of intermediates only. The major portion of the total output of intermediates is probably consumed in the dyestuff industry, although a large amount, especially trinitrotoluol, falls in the category of explosives. There is a constant increase in the variety of intermediates and chemicals produced in this country for making colors. Dyestuff manufacturers are now producing large quantities of toluidines, resorcin, xylidine, dianisidine, naphthylamine, diphenylamine, tolidine, benzidine,, benzaldehyde, benzyl chloride, nitrobenzol, nitrotoluol, H-acid, phthalic, metanilic, sulfanilic, and naphthionic acids, naphtholsulfo acids, naphthylaminsulfo acids, and amidonaphtholsulfo acids, Schaeffer's salt, paranitraniline, dimethylaniline, and numerous others.

A glacial acetic acid plant of large capacity is expected to begin operation in September, and will be of the greatest assistance to the industry in general.

Artificial Colors.

The current monthly production of 46 manufacturers of finished dyes is at the rate of 5,000,000 pounds, or 60,000,000 pounds annually, individual outputs ranging from 600 to over 2,000,000 pounds each. This does not include any estimate from one plant of the first magnitude whose entrance into the industry has just been announced to the trade, or a score of smaller projects organized but not yet in full operation. The total shown includes only the figures given by the factories of actual production for the current calendar year, and makes no allowance for many plants now in course of construction which will soon be producing colors on a commercial scale, nor for the output of many dyes still in the experimental stage. These facts leave no doubt that our present annual domestic output greatly exceeds in quantity the entire consumption of artificial colors in the United States during the year 1914, estimated at 60,000,000 pounds, and is probably equivalent to the current annual consumption, which is considerably in excess of that for 1914. The returns further show beyond all question that a vast amount of technical talent and native inventive genius are now being concentrated on experimental research to perfect processes of production, improve quality, and enlarge the variety of dyes so as to include not only the more complex known colors currently used in Europe but possible new ones.

Coal-tar dyes in a variety of colors suitable for leather, textiles, straw, paper, inks, stains, pigments, varnishes, waxes, feathers, furs, and for many other purposes are now regularly obtainable from domestic sources. Several manufacturers carry full lines of direct, acid, basic, chome, oil, and sulfur colors, while others confine their efforts to improving and extending their output of particular groups. Prominent among the colors produced are nigrosines, indulines, triphenylmethane dyes, safranines, eosines, chrysoidines, rhodamines, rosanilines, direct fast reds, browns and yellows for cotton, fast chrome colors for wool, Sudan colors, basic violets, synthetic indigo, alkali blues for the silk and woolen industries and also for the lithographic trade, metanil yellow, methyl violet, methylene blue, benzopurpurine, benzo sky blue, primuline, naphthol green, rose bengale, gallocyanine, and special chrome and khaki colors.

Considerable attention is being given by about a dozen firms to developing as rapidly as the requisite intermediates are available the triphenyl-methane dyes, particularly fuchsine, methyl violet, methylene blue, magenta, and malachite green. Their output of many of these colors was not separately stated by some of the factories. The itemized figures given by only a few of the plants, however, show a monthly production of this series of colors amounting to 62,200 pounds. Of this quantity 18,200 pounds represent methyl violet and 13,450 pounds methylene blue. Two manufacturers specialize on the needed intermediates for these dyes.

There is a largely increased production and variety of reds, yellows, and scarlets, prominent among them being parareds for the printing trade, lithol red R, paramagenta, croceines, fast red Bordeaux for wool, acid reds and scarlets, wool scarlet, Biebrich scarlet, chrome yellow, metanil yellow, chrome orange, and brilliant orange. A wide range of fast reds, blues, greens, yellows, blacks, and grays for cotton is also available.

Colors now produced on a commercial scale that were not made in this country until recently are alizarin blues, browns, and yellows for calico printing, and for wool; paracolors for lakes or pigments, vat dyes (sometimes called indigoids) for cotton shirtings and ginghams, synthetic indigo, rhodamine, patent blue, and Biebrich scarlet.

Vegetable Colors and Extracts, Mineral Dyes, Lakes, and Pigments.

Present production and new developments contemplated include blacks and greens in natural colors for calico printers, a special logwood blue, special mordants for dyeing new shades in direct cotton colors, khaki dyes, cutch, archil, and logwood extracts, and cudbear powdered, orange, and lemon flavines, Osage orange in a variety of shades, American sumac extract, indigotin, and natural indigo shades. It is stated by several plans that their output depends on the domestic demand, ample facilities being available for a largely increased production at any time. Some operate at half capacity, while others are running 24 hours a day.

One firm is making sulfur brown (not a coal-tar product) on an extensive scale, while another company is producing mineral colors in standard shades for wool.

Soluble Prussian blue, Chinese blue, pigment brown, lakes in all the principal colors, paratoners, dry colors, and dyes for lake makers are specialties handled by different manufacturers.

Photographic Developers, Pharmaceuticals, Synthetic Perfumes, etc.

The urgent demand for photographic developers since the war began has greatly stimulated the production of hydroquinone, p-amidophenol, metol, amidol, and reducin. Single firms report monthly outputs of 1,000 to 15,000 pounds each of hydroquinone.

Manufacturers of coal-tar by-products are also marketing quantities of salicylic acid and its derivatives—particularly acetyl-salicylic acid (aspirin)—phenacetine, acetphenetidin, acetanilide, and other medicinals.

One maker of intermediates is producing the synthetic perfumes nerolin and bromelia. Another firm includes vanillin, used in flavoring extracts, in its list of products, and also saccharin.

Future Developments Contemplated.

The most striking feature brought out on the forms filled in by the dyestuff manufacturers is the marvelous growth of the industry and the plans in process of formation for its continued expansion in both domestic and foreign fields.

Announcement has been received of the entrance into the dyestuff industry of the leading company manufacturing explosives, fully equipped with a chemical and engineering staff, plant, and laboratory facilities, and an adequate commercial organization to meet the demand for colors on a vast scale. Other new plants in process of construction or to begin operations before 1918 are two for coal-tar crudes, one for anthracene, one for glacial acetic acid, four new buildings for aniline dyes, one for chrysoidine and methylene blue, one for nigrosine, induline and magenta, and one for nigrosine only. A producer of direct, acid, and chrome colors expects to double his present output of nearly half a million pounds annually inside of 12 months. One plant making methylene dyes is planning to double its capacity, two others making aniline colors will also double their capacity shortly, one manufacturer expected to have patent blue and fuchsine on the market after July, one of the larger corporations is now making auramine and lanafuschsine on a small scale and installing equipment for their increased output, and another contemplates the manufacture of primuline in considerable quantity. A producer of high-grade colors for silk is enlarging his factory and contemplates the early production of safranine and a suitable plant for the extensive manufacture of other aniline dyes.

Notations on a very large proportion of the forms returned show that experimental research is in progress on a great variety of products that are now being manufactured on a semicommercial scale with a view to increasing production as the processes are worked out in the different establishments.

Foreign trade opportunities published in *Commerce Reports* during the past few months from agencies in Norway, Spain, Brazil, Venezuela, and several from India, indicates foreign fields awaiting exploitation in this line, while recent sales of such products have been made in England.

Dyes and dyestuffs exported from the United States during the fiscal year ending June 30, 1917, were valued at $11,710,887 as compared with $5,102,002 for 1916. Beginning with July 1, 1917, the classification for monthly statements of exports will include under dyes and dyestuffs the subdivisions, alinine dyes, logwood extract, and all other shown separately.

A list of manufacturers in the United States producing coal-tar crudes, intermediates, artificial colors, and vegetable dyestuffs, and extracts may be obtained from the Bureau of Foreign and Domestic Commerce or its district and co-operative offices by interested users of such products.

Standards of Dye Strength in England.

Not only in the United States, but also in Great Britain, the question of standardizing dyestuffs has become a topic of keen discussion. In the following article *The Manchester Guardian* pictures very fairly the situation as it concerns both British producers and consumers of colors:

"Pre-War" Standards.

In a dyestuff case at the recent Assizes, counsel made great play with the phrase which has attained a significant currency in the trade—the "pre-war standard"; but the legal mind does not succeed as a rule, in throwing much light on subjects of this kind.

It appears that our German enemies had exported their dyestuffs to use in such a state of purity and uniformity that the standard cannot now be reached in spite of all our endeavors, and that no sample of dye that was not sanctified by the words "guaranteed pre-war standard" could be expected to be of first-rate quality. If that be so, it is not a very proud position to assume for a trade which has received national benediction and support, and which might almost be called now the spoiled child of British industry. Is it the fact that our manufacturers of dyes, handicapped as we know they are in some directions by lack of raw material, are deliberately adopting for such dyes as they can make a lower standard than that set up in pre-war times?

In the first place, it is a little amusing to those who knew something of the inner workings of the German firms, and who would not have been surprised in those days to have been comparing half a dozen different standards of the same thing or as many complaints of variations from standard, to find that "pre-war standard" is a name to conjure with. It is true that in such stock colors as direct cotton blacks and blues, benzopurpurine, sulfur blacks and alizarin, in which price conventions had been established, there was a fairly exact standardization. But in other quite common colors, such as wool scarlets and direct cotton pinks, there were variations of as much as 20 per cent between the regular standards of first-rate firms. Further, even in such a stock color as direct cotton black, one maker would offer one shade in two or even three different standard strengths, varying at least 50 per cent. Which of these standards now represents German orthodoxy?

It must be borne in mind, of course, that, for practical reasons and with one or two exceptions, dyestuffs are never marketed in the chemically pure state, but are "reduced" with various colorless diluents, which do not affect the coloring principle in any way. In other words, they are "standardized," and each maker adopts his own standard of strength, which, under pressure of competition, tends to approximate in relative price to the standards of other firms. Unfortunately for the dyer, a difference of a halfpenny per pound is much more obvious to him than a corresponding difference of 10 per cent in the strength, and, therefore, it not infrequently happens, and it has become a more common practice during the dyestuff famine, that a quantity of dye will be passed from hand to hand and further diluted in the process, or an odd parcel will be made up to a full hundredweight. The dealers have increased in number, while our sources of supply have decreased. This process of dilution is not in any way detrimental to the dye; it remains the same dye, and may rightly carry the same name, but it is not "pre-war standard." Where a mixing of dyes is in question, the matter is not quite so simple; insead of a comparatively innocent dilution, the dyer may receive an article which would be more correctly described as adulterated if the fastness and chemical properties, or even the shade of the dyeing, should be deteriorated by the admixture. Such an adulteration is much less easy to compute or even detect than a mere dilution, and in some cases the impurity may be present as a by-product of the manufacture, which, with more experience, the manufacturer may be trusted to eliminate. But in every event it is highly desirable that the dyer should make preliminary tests of every parcel of dye he proposes to buy, both to ascertain its coloring value and also that it will have the properties of fastness which he associates with the name under which it is sold. A dyestuff might be of full strength, and yet very far from "pre-war standard."

It is clear from these considerations that the phrase is only a very rough indication of the strength of the dyestuff, and indeed it is to be feared that it is very loosely used at times, and that under the abnormal price conditions ruling little consideration can have been paid to standards of any kind. Standards have no value apart from price, and standardization will only become of increasing importance again under the pressure of competition. In the meantime, the British manufacturer of dyes sets up his own standard of strength to work to. It may be comforting to the dyer to know that that British standard is comparable to a normal German standard, but more comforting still is the knowledge that the manufacturer supplies him at a price which is usually well below what the same dye would fetch in the open market at the present time. In other words, the manufacturer's output is well above the market standard of strength-value.

The Dyeing of the New Standard Khaki in England.

By C. M. Whittaker, B. Sc.

After two years and nine months of war the dyeing of khaki on loose wool is attaining a new significance because of the control of the wool trade by the Government. Manufacturers who have hitherto taken no part in the production of khaki cloth are willy-nilly now having to turn their attention to this line of business. Seeing that the State control of wool is making the purchase and use of wool for other purposes than military equipment increasingly difficult, there is no doubt that khaki orders will be a welcome means of keeping machinery running.

Vexatious Tests.—The dyers have at last been called into consultation on the best methods of obtaining the fastest results, taking into full consideration the uses to which the cloth will be put and the influences which it will have to resist. It is, therefore, sincerely to be hoped that many of the absurd tests to which khaki was submitted before the war will now disappear, never to be revived.

A big step in the improvement of the fastness of khaki has been taken in forbidding the use of logwood, gallocyanine and acid wool colors, because the small percentage of hematine or gallocyanine necessary in the dyeing of khaki was inevitably fugitive. The steps now being taken by the authorities will gradually eliminate other colors of which the fastness to light is not above suspicion. There are now ample supplies of other colors on the market, which are superior in fastness to light, and the continued use of the looser colors cannot be justified by the excuse that supplies are short.

The efforts of the authorities to obtain a standard shade of khaki of a standard fastness to light and milling will be slow in yielding results, and will require to be continued for some considerable time before they reach full fruition. Indeed, it is questionable whether the object to be attained is practically possible with several dyers and several manufacturers handling the wool. If six manufacturers were given wool of identical khaki shade, it is doubtful if two of them would produce the same ultimate result, owing to differences in their milling and finishing processes. Indeed, no one manufacturer will, for the same reason, deliver all his pieces to exact shade. There will have to be give and take in the matter, but there is no doubt the efforts now being made will effect a great levelling-up in the fastness of the khaki produced, though this will only be evident as the old contracts are worked off and deliveries of the new contracts under the new conditions begin to be made.

Single Bath Desirable.—The object of all these efforts is to reduce the multiplicity of shades demanded by the dyers—the number is surprisingly large—and so to obtain increased production to counterbalance the increasing shortage of labor. It also logically follows that the quickest method of dyeing should be adopted for the same reason, despite the opposition of those dyers who are still obsessed by the virtues of the chrome mordant because it is clear that a single bath method must beat a two-bath process bath from the point of view of production, labor, time, and steam.

The new khaki standard may be and is being produced in a variety of ways, but the following single bath recipe has been largely adopted, and is yielding good results on the big scale in a quick and cheap manner, while the results are fast both to milling and light. For 100 lb. cross-bred wool, weigh out:

4 lb. 5½ oz. Khaki Yellow WN paste.
1 " 6½ " Khaki Brown W paste.
1 " 3 " Khaki Green W paste,

and dissolve in water at the bottom of the cistern by boiling for ten minutes, then fill up, and add just before the wool is entered:

2 lb. bichrome,
5 " ammonium sulfate,

make slightly alkaline with ammonia before adding to the dyebath. Enter the wool not below 140° F., raise quickly to the boil, and boil one hour. It will naturally be understood that different qualities of wool may require slight alterations of the above qualities.

The observance of the following points will ensure good results every time:

The colors must be boiled for ten minutes in order to dissolve them completely; Khaki Brown W is the color which requires this.

Owing to Khaki Brown W commencing to fall out of solution below 100° F. the wool should always be entered well above this temperature, so that it does not cool the bath below 100° F., because if the Khaki Brown W has been allowed to fall out of solution it does not give the same color value.

While, in our opinion, ammonium sulfate gives the most level shades, its use is optional, and it may be replaced by acetic or formic acid. If these two acids are used, they should not be added until the bath has boiled half an hour. Sulfuric acid must be used with the greatest care, or else the shade will be turned too yellow. Some dyers use it toward the end of the dyeing fully to develop the green tone, but it must be carried out with extreme care.

When to Add Bichrome.—If it is desired to enter the wool boiling to get it under then keep off the bichrome and ammonium sulphate until the wool has been boiled under. The same precaution should be taken in machine dyeing in that the bichrome should not be added till the wool has become thoroughly saturated with the dye liquor, and the ammonium sulfate should be added after the bichrome has been pumped through for ten minutes. Extracted wool should always be neutralized before being dyed by this process. When dyeing limed or skin wool it should be noted that the shade takes longer to develop owing to the presence of the lime, and that it will in all probability require slightly more acid.

Finally, it must be noted that Khaki Green W must not be dyed in copper vessels, and that owing to its sensitiveness to copper we do not recommend its use for yarns or pieces. This sensitiveness to copper has made some people chary of using it on loose wool, but I would wish them to note that once the chrome lake of Khaki Green W has been formed it is not sensitive to copper. This may easily be tested by boiling a chromed khaki green shade with copper sulfate, and the copper will be found to have no effect on the shade. Wrap a piece of copper wire in flannel dyed with Khaki Green W and bichrome, and leave it in a strong soap solution over night; it will be found that it has no effect on the green.

It should also be noted that practically all the greens, blues, and blacks on the list of approved colors are distinctly sensitive to copper.—*Dyer and Calico Printer.*

The Bayer & Co. Works at Rensselaer.

The works at Rensselaer, N. Y., of the Bayer Co. are to be notably enlarged by the erection of three additional buildings. The output of dyes, as well as of synthetic medicinals by this company has done much to lessen the acuteness of the dyestuff shortage of the past two years. This increase in the facilities for manufacture will be welcomed by all depending upon the special group of colors made by the Bayer Co., which has hitherto specialized largely in the Nigrosines and Indulines, Chrysoidine, Bismarck Brown, and some of the standard triphenyl-methane dyes.

Colors for Army Uniforms.

Exceptional interest is felt in the requirements of the War Department as to color in connection with the vast number of uniforms now being ordered for our expeditionary force.

The *Textile World Journal* furnishes the following data on the subject which tend to show that the standard "olive drab" is produced in a thoroughly satisfactory manner by our domestic dyes, both synthetic and natural:

A certain firm manufacturing dyes has forwarded samples dyed with its colors to the local quartermaster's department to be submitted to the official tests. In this way it is hoped to obtain a definite statement as to the suitability of those particular dyestuffs. The wisdom of this procedure is emphasized by the representative of this firm, who states that there is no use recommending colors to customers as being available for meeting Government requirements unless definite knowledge of this fact is at hand. The tests used by the Government are soap and soda tests and 30 days' exposure to sunlight. The colors most in demand for producing an olive drab on wool to meet these tests are the chrome colors. These must be understood to be different from the actual alizarin dyes, or those produced from anthracene. There is a range of so-called "alizarin" and "anthracene" colors which have begun to be produced in this country. These are applied on a chrome mordant. From all reports, these have passed the tests satisfactorily. Despite the great demand for dyes of this nature, the few firms making them are keeping up fairly well with their orders.

As far as the use of natural dyes is concerned, a factor in the local market wrote to the Quartermasters Department inquiring if dyewoods were acceptable for Government orders. The answer was that so far there had been no embargo placed upon the use of natural dyes and that the only guide used by the department was the selection of dyed samples best meeting the standard requirements. In other words, it appears that the original method of dyeing is not closely scrutinized, but that judgment is passed upon the actual resistance shown by the samples submitted. Swatches are taken individually and must meet specifications. It is a known fact that osage orange has come up to Government specifications and that in some cases it has been found preferable to fustic, as there is a reddish constituent in the latter dyewood which is destroyed by the test. In all dyeing, however, much depends upon the care with which the fabric is colored, as the same products may give varying degrees of fastness when dyed under different conditions. This fact cannot be too strongly emphasized. Another natural dye which is being used, much to the surprise of factors in the dyewood market, is quercitron. This has generally been regarded as not suitable for the dyeing of fast shades, but it is known to have given satisfaction in the dyeing of blankets for Government use.

The Combination of the Leading German Manufacturers of Artificial Colors.

The necessity of unity and close co-operation on the part of the great German dyestuff companies, in order to recover to some extent the vast trade in all countries, which ceased soon after the beginning of the war, was recognized late in 1915. This necessity was intensified by the fact that powerful and promising efforts were under way to establish independent, self-contained, domestic color industries in our own country, in Great Britain, France, Japan and in other lands.

As a result, the leading firms entered into a very close combination, the natural effect of which will be to bring the rapidly growing coal-tar color industry in the United States, as well as the similar industries in other countries, face to face eventually with a single, giant organization, bent upon exerting every possible effort to regain the lost territory.

In a recent number of "Commerce Reports" (July 30) Consul W. C. Teichmann, who was stationed at Mannheim, across the river Rhine from the great works of the "Badische" Co., furnishes the following interesting description of the mechanism of this new combination:

Among the many economic changes that the present war conditions have brought about in Germany, the combination of German dyestuff interests, effected in 1915 and operating since January 1, 1916, is of special importance to Americans, because it means a formidable competitor for our infant American dyestuff industry in every foreign field, as well as in our own domestic market. In a smaller degree it also will bring future competition to other chemical industries in our country which have prospered during the war, as the German concerns that have been combined are also producers of pharmaceutical chemicals.

The rapid growth of the American dyestuff industry during the war has been given serious attention by the German concerns that formerly controlled our market, and has assisted in uniting these great rivals in Germany for mutual protection

Realizing the difficulties of reconquering the lost markets of the various foreign countries after the war, the German dyestuff manufacturers in the fall of 1915 organized a combine of the seven leading companies, which practically control the output, and pooled interests to the extent of securing uniform prices and wages, systematizing production, and also insuring a harmonious policy for all other interests involved. This implies uniformity in all endeavors to regain the former German foothold in foreign markets, and will apply to the new competition in the American market particularly. The importance of German exports in chemicals prior to the war can be seen from the statistics. Their annual averaged about $214,000,000, according to estimates of German trade organizations.

The concerns that entered the combine at that time, with their annual share of profits guaranteed during the first two years, were:

Companies.	Capital.	Average share of profits for two years. Per cent.	Later share. Per cent.
Hoechster Farbwerke	$11,900,000	24.82	25.02
Badische Anilin & Sodafabrik	12,852,000	24.82	25.02
Bayer, Leverkusen	......	24.82	25.02
Leopold Cassella & Co., Frankfurt	......	10.00	Not fixed
Aktiengesellschaft fuer Anilinfabrikation Berlin	4,712,400	8.04	8.14
Chemische Fabrik Griesheim	1,904,000	7.50	Not fixed
Chemische Fabrik vormals Weiler ter Meer			
Totals	......	100	100

Considerable difficulty was encountered in dividing the future profits, but the figures given were finally decided upon, together with an agreement, the essential features of which were as follows: It is to be binding for 50 years beginning January 1, 1916. While the separate organization of production of each concern is to be maintained, risks in business with foreign countries are to be jointly and proportionately carried by all members of the combination, accounting for the contemplated competition in foreign markets, in both "hostile and neutral countries" after the war. The distribution of the profits is to be based upon a certain "key" of calculation, however, not figuring on the entire production, but leaving out of consideration at first various special lines which are to be reckoned with after the expiration of a certain transitory period. For the Hoechster Farbwerke this involves separate profits from the manufacture of calcium carbide, and certain other products made therefrom; for the Badische Anilinfabrik, Bayer, and Berlin-Anilinfabrikation, the profits derived from the manufacture of synthetic ammonia and the respective inorganic compounds produced therefrom.

The "Badische" Co. has so successfully applied the Haber process of extracting nitrogen from the atmosphere and the production of synthetic ammonia therefrom since 1913, that while the ammonia output amounted to only about 30,000 tons in that year, it increased to 60,000 in 1914, 150,000 in 1915, and 300,000 in 1916, with an estimated figure of 500,000 tons for 1917.

The calculation of the table of profit percentages for the German combine was based upon an older "key" of the union of the Badische, Bayer, and Berlin. In the earlier combine the first two received 43 per cent. each, and Berlin 14 per cent. In order to enable the admission of the big Hoechster concern in the percentage to be made, that company increased its capital by $952,000, free from taxes and dues, at a market value of 200 per cent. per share. This favorable issue of new stock formed the equivalent for the transfer by Leopold Cassella & Co. of a part of its entitled percentage, according to its recently increased output, to the Hoechster concern, involving about 5 per cent. of the profits, so as to reduce the Cassella percentage from 15 to 10 per cent. In return Cassella receives in addition to the new stock of the Hoechster concern for a period of 10 years a special profit up to three-fourths of 1 per cent. of the total profits realized by the entire combine, as an indirect profit.

Another interesting subsidiary agreement was made with the large concern of Kalle & Co. in Biebrich on the Rhine. Kalle was included in the older Hoechster-Cassella agreement to the extent that the shares formerly in part held by Cassella were transferred to the Hoechster concern, which is now in possession of the entire capital of $1,428,000 of the Kalle Co., and hence also includes in its profit percentage the participation of Kalle & Co.

Adding to the 74.46 percentage of Hoechster, the Badische Anilin, and Bayer those of Berlin and of Cassella, the five concerns represent 92½ per cent. of the total profits of the new combine. Griesheim and Weiler ter Meer receive about 7½ per cent., probably yielding 6 per cent. to the latter, and 1½ per cent. to the former.

Thus a formidable understanding has been reached between the manufacturers of dyes and colors which can not fail to affect future prices and the export policies to be followed after the present war. Although German exports of chemicals received an effective setback as a result of the shipping hindrances encountered since the outbreak of the war, and the vigorous enforcement of the German embargo on many articles in these lines practically kept them out of the foreign markets altogether, it is predicted that nothing will be left undone which is needed in the attempt to reconquer the lost position.

It would seem that the loss of the large export business would have reduced the profits and dividends of the large companies that are in the combine, but contracts for army and hospital supplies have proved to be so valuable as to result in an increase rather than a diminution of profits since the war broke out, as shown by the figures for two of the concerns.

The Hoechster Farbwerke recorded net profits of $3,736,600 in 1915, as against $3,001,180 in 1914. Its dividends were 20 per cent. in 1915, 20 per cent. in 1914, and 30 per cent. in 1913. The Bayer Co. had net-profit figures of 4,969,440 for 1915 and $3,689,000 for 1914. Its dividends were 20 per cent. in 1915, 19 per cent. in 1914, and 28 per cent. in 1913. The Badische Anilinfabrik showed net profits of $4,519,540 for 1915 and $3,760,400 for 1914, the 1915 dividend, however, being 20 per cent. only, as against 19 per cent. for 1914 and 28 per cent. for 1913. Extensive enlargement of its plant and the rapid growth of its business at Oppau on the Rhine, where the process of nitrogen extraction from the atmosphere had necessitated the erection of large buildings, diverted some of the profits from dividend distributions; hence the lower dividends after the war broke out.

All German chemical concerns, small as well as large ones, have been favored with Government contracts for war supplies, so as to prevent their financial embarrassment. Industries which formerly manufactured goods in lines not available for war supplies were induced to change their plants somewhat in equipment so as to be able to furnish some kind of war material. Thus the absence of export facilities failed to destroy German industrial competitive power, and upon the conclusion of the war this factor must again be reckoned with.

Organization by combination of interests has not been confined to chemical lines, but is going on in various other industrial branches in preparation for tremendous efforts to regain foreign markets.

Reserve Stocks of Artificial Dyes in China

When the exportation of German synthetic dyes ceased in 1915, there was a most energetic hunt in out-of-the-way parts of the world for scattered stocks of colors, the owners of which could be tempted to part with them at elevated prices. Considerable amounts were found in Mexico, Central and South America. China, however, was the most productive field, and the quantity there secured was remarkably large.

The following report from the American Consulate General at Shanghai offeres an interesting picture of the general movement:—

"The declared exports of aniline dyes and indigo paste invoiced at the American consulate general at Shanghai for the United States during the years 1915 and 1916 and the first five months of 1917 were as follows:

Kind.	1915		1916		Jan. 1 to May 31, 1917	
	Pounds.	Value.	Pounds.	Value.	Pounds.	Value.
Aniline dyes	1,301,312	$1,865,723	201.771	$540,227	2,000	$22,284
Indigo	2,441,821	2,482,129	406,466	546,471	....	....
Totals	3,743,133	$4,347,852	608.237	$1,086,698	2,000	$22,284

"These dyestuffs were all of German origin, as the trade was controlled by firms of that nationality up to 1914. When the war began and the original sources of supply were closed, consumers in the United States turned to other available stocks. The result was that during the next two years there were large exports from Shanghai, but at abnormal prices, as a number of Chinese firms cornered the market.

"Quotations on all grades increased many times and were subject to violent fluctuations. For fast indigo blue, in cases of 200 8-ounce cans, one firm charged 45 taels ($28.54 at $0.632) per case before the war, 270 taels ($155.28 at $0.5751) on January 17, 1916, and 400 taels ($301.20 at $0.753) on September

18, 1916; another firm, 450 taels (258.80 at $0.5751) on January 17, 1916, and 700 taels ($402.57 at $0.5751) on February 1, 1916.

"China magenta, in cases of 200 8-ounce cans, was quoted by one concern at 110 taels ($69.52 at $0.632) before the war, at 600 taels ($345.06 at $0.5751) on January 17, 1916, and at 1,300 taels ($978.90 at $0.753) on September 8, 1916; another quotation was 750 taels ($431.33 at $0.5751) on January 17, 1916, and 950 taels ($546.34 at $0.5751) two days later.

"The examples given show not only the fluctuating and generally increasing prices of silver, but also the wide differences in quotations by separate firms on approximately the same dates, a proof of the uncertainty and instability of the market.

"The almost entire disappearance of these goods from the list of exports to the United States since the first of the present year may be ascribed to (1) the high rate of silver, resulting in increased gold prices (unfavorable to exports); (2) the excessive prices, in local silver currency, demanded by the Chinese merchants now holding stocks; (3) the prevailing high freight and insurance rates and lack of shipping space; and (4) the probable increase in the domestic production of dyestuffs in the United States."

NATURAL DYES

The Manufacture of Archil Extract in the United States.

The use of the natural dyestuff archil (orchil, orseille) dates far back. Despite the pronounced fugitive character of the bright red and violet shades which it yields there is a constant and regular demand for the dye, chiefly for use in combination with other colors on wool and silk. Fabrics and yarn dyed with perfectly fast colors seem to gain very materially in luster and brilliancy when passed through an archil bath. There is, also, our extended use in producing certain brown shades, both in dyeing and calico printing, which are fairly permanent to light.

The coloring matter is obtained from various lichens, *Roccella tinctoria, Roccella fuciformis, Roccella Peruviana,* and allied varieties, which grow freely on rocky sea coasts, notably in the Mediterranean, in the Azores, Mozambique, Zanzibar, Madagascar and Ceylon The raw material is pressed into bales and sent to European centers of distribution. Prominent among the latter are London, Havre, Lisbon and Hamburg.

The extraction of the coloring principle in a form suitable for the dyer's use has been localized chiefly in England, France and Switzerland. It is found in commerce in the form of liquid extracts of varying strength, of paste, and of the dry powder known as cudbear.

It appears that the peninsula of Lower California is an abundant source of the lichens in question. American capital has secured control of the best locality. Instead of shipping the crude material to Europe it is sent to San Diego, California, near which the Lower California Chemical Co. has erected a large plant for the purpose of extraction.

The most promising source of archil in Lower California is in the region about Magdalena Bay, where *Roccella Peruviana* is found in great quantities growing upon shrubs and bushes exposed to the spray and mist of the Pacific ocean. Scattered occurrences of the parasitic moss-plant are found all along the Pacific slope, but nowhere in such abundance as in the so-called "Zona orchillera" around Magdalena Bay. In this tract about 100,000 tons of the plant are ready for harvesting. It reappears rapidly. Within three or four years after a tract has been picked clean a new crop is ready for collection.

The operation of harvesting is quite simple. The lichen is torn from the trees or bushes upon which it is found and allowed to dry upon the ground for a few days. The daily amount collected by a laborer ranges from 100 to 200 pounds. When well dried it is pressed into bales of 550 to 650 pounds each, and is ready for shipment. Prior to the war archil collected at this point sold for $23 per ton, including freight to European ports. Prices for the same material on the Peruvian coast, f. o. b., ranged from $22 to $48 before the war.

This one source is sufficient to supply all of the archil extract used currently in the United States, which amounted to about 250 short tons annually prior to 1915, but which has been materially augmented since then.

The plant of the Lower California Chemical Co., for the extraction of the coloring matter, is located at National City, near San Diego, Cal. The operations are relatively simple, but require exceedingly careful supervision in order to assure purity and uniformity of product.

As in the case of natural indigo the coloring matter is not present as such in the lichen, but results from a process of oxidation. This is carried out with free exposure to the air, but requires the simultaneous action of ammonia. The works of the company are equipped with capacious vats, in which the archil plants, after having been carefully cleaned and ground to a coarse powder, are allowed to remain for several weeks in contact with very dilute ammonia and under constant stirring.

The orsellinic acid in the lichens, as a result of the process of fermentation which takes place, splits off CO_2, and forms orcinol, or m-dihydroxytoluene, $C_6H_3(CH_3:OH:OH = 1:3:5)$. This, in turn, in the presence of ammonia, changes into orcein, which appears to be a mixture of reddish $C_{28}H_{24}N_2O_7$ and yellowish

$C_{21}H_9NO_6$, along with a coloring matter similar to litmus.

The thick paste remaining in the vats forms the simplest commercial article. Dried and powdered it is known as cudbear. The paste is also extracted with water, and the reddish-violet solutions, in various degrees of concentration—the strongest being thick syrups—are preferred by many dyers.

It is a source of satisfaction to see this manufacture of the well-known vegetable coloring matter firmly established on American soil, and we confidently look forward to such an expansion of the industry that its output may contribute to the growing volume of our export of American-made dyes.

We are indebted to Mr. C. W. Hill, president of the company engaged in this undertaking, for several views illustrating the collection of the raw material.

T. H. N.

Autumnal Foliage as a Source of Dye.

The peculiar conditions of the past three years, in connection with the supply of coloring materials for textile and allied industries, have stimulated to a remarkable degree the search for new dyes in the vegetable kingdom, as well as the more thorough and intelligent utilization of those already well known to the colorist. In South America and in India the efforts have been numerous in this field. In the United States they have been not less so, although in most cases little publicity has accompanied the search.

Osage orange is the most striking example of the development of an entirely new source of a dye, already well known in the fustic of tropical America. Of notable importance is the wide-spread demand for the Quercitron of the American black oak, and the more general recognition of its helpful and permanent qualities in a comprehensive scheme of dyeing.

The most recent advance in this province is the detection of a valuable dyestuff in the autumnal foliage of our American forests, more especially in that of the maple. The dried leaves of this tree, when subjected to the customary methods of extraction by boiling water, yield a product constituting in the dry form about 18 per cent of the original weight. This product is a genuine dye, imparting to animal fibers beautiful shades of brown, of absolute fastness to light, washing, etc., without the use of a mordant. The range of tints is increased by the use of the ordinary mordants. The ease of dyeing without the use of metallic mordants is evidently due to the presence in the color extract itself of a considerable amount of tannic acid.

The application to cotton is not productive of as pronounced tinctorial results, as in the case of wool or silk, but there appears to be a distinct field here for its use, especially in combination with other coloring matters.

In connection with silk dyeing, this new material promises to play an important role for purely weighting purposes. Silk fibers absorb an appreciably larger amount of the maple extract than is the case with gambier, now so largely used for weighting. The color imparted to the silk is somewhat darker than in the case of gambier, otherwise the fiber adapts itself with the same ease to the subsequent operations involved in dyeing and finishing.

An interesting fact in connection with this new color is that the discovery was made by a woman, Mrs. Edith O'Neill MacDonald, of St. Regis Falls, N. Y. She has christened the product "Gold Leaf," a picturesque but quite appropriate designation, for the substance, especially for some of the lighter shades obtained in its use.

Mrs. MacDonald is a lady well-known in northern New York as a writer and speaker. Her own account of the discovery is of so much interest that we reproduce it:

"I canvassed the wants of America as set forth in the newspapers and finally decided the dye shortage at the time was the most acute situation (we had potatoes then), and the most possible and probable field of discovery. Chronic inventors possess a power of concentration that amounts to genius. Genius is only acute observation and powerful concentration on a given subject. But anybody with an average amount of intuition and the power to adjust the mental focus to one particular field of vision can indulge in acute attacks of invention. Having decided to have such an attack, I adjusted my mental focus on the dye field. I looked at everything through color glasses, so to speak. I read newspapers, magazines, and technical journals and searched my immediate surroundings for something that looked like dye.

"Then there came a north country October windstorm that tore all the leaves from the trees. Following it, a continued rain saturated them and glued them to the cement walks. Finally the sun dried them, and gentle breezes lifted and whirled and scattered them into sheltered corners. But instead of 'Footprints on the Sands of Time,' they left leaf-prints of this dye of mine. Thousands of people in the north country walked over these prints, and have walked over them for many years. I have myself, and seen them only as an artistic but empty outline. But this day my mind was adjusted to a dye focus, and at sight of the dainty brown prints I leaped at the possibilities they might contain. I gathered an armful, and in twenty-four hours I had an array of tints of gold that rivaled the sunshine—gold that would neither boil out, wash out, nor fade out, though I tried it in weeks of sunlight.

"Immediately I communicated with the dyestuff expert of the Bureau of Foreign and Domestic Commerce, whose opinion is so highly appreciated in such matters. Under his tutelage I acquired a more or less intimate and accurate knowledge of dyeing and textile chemistry. I mastered the use of mordants and six weeks later I had finished a demonstration that contains every possible shade ranging from a shimmering, glistening gold to the darkest seal brown, as well as grays and taupes. In this demonstration I used wool, silk, velvet, feathers, and paper, also demonstrating the use of the solid extract as an ink and water-color paint. The Patent Office examined the dye, tested it, and allowed my claim without delay."

This new color may be of pronounced assistance in view of the rapidly increasing demand for khaki shades. The one limitation upon its otherwise so easy manufacture is the fact that the abundant raw material can be collected from our maple forest only during the late autumn, after the chlorophyll present in the leaves has undergone radical transformation.

In interesting connection with the above we quote the following from a recent issue of *The Chemical Trade Journal* of London:

H. M. Consul-General at Seoul has forwarded particulars regarding the production of dyestuffs in Corea from the leaves of a species of maple tree, known to Coreans as the "Shinnamu." This tree is very common throughout Corea, and, according to the Director of the Central Technical Institute of the Governor-General of Corea, is not found elsewhere, except to a certain extent in that part of Manchuria immediately to the north of the Yalu River. The official referred to states that if the dye should prove of commercial value, it could be produced in very large quantities in Corea. The cost of production, according to the same authority, is approximately 25 sen (about sixpence) per pound. With colors obtained from the "Shinnamu" extract cotton goods can be dyed black, indigo, dark gray, and khaki. In dyeing silk and pongees, black only can be utilized, and the chief value of the extract is for loading purposes, silk yarns or materials becoming over 30 per cent heavier after treatment. H. M. Consul-General has also forwarded a sample of the "Shinnamu" dye, together with samples of cotton yarns dyed with it, in four colors.

"Particulars of the methods of using a yellow or khaki dye produced in Corea from the flower of the "Enju" or "Pagoda Tree" have also been received from H. M. Consul-General. This tree is said to be very common both in Corea and in the district of Manchuria immediately north of the Yalu River. Silk, wool, and cotton are all susceptible of treatment with this dye, a sample of which, together with specimens of various threads and yarns treated with it, have been furnished.

"The above-mentioned particulars may be consulted, and the samples referred to inspected, at the Department of Commercial Intelligence, 73, Basinghall Street, London, E. C. 2."

There is no mention in the above of the source of dye being limited to autumnal foliage. The value of the extract for loading or weighting silk would indicate, however, a close relationship with the American product.

SYNTHETIC DRUGS AND PERFUMES PHOTOGRAPHIC DEVELOPERS

Salvarsan of Domestic Make.

Prior to the war the world depended upon the great chemical works at Hoechst, in Germany, for its entire supply of the important synthetic medicinal, salvarsan. A few consignments to this country were permitted to pass by the British Government. The total amount thus received was far below the quantity normally required by the medical profession, and the inability to secure supplies has caused serious hardships.

Under the circumstances, Mr. Herman A. Metz, of Herman A. Metz & Co., the American agents of the Farbwerke-Hoechst Co., took the necessary steps to have the manufacture of the compound placed upon an industrial basis in this country. A suitable plant was erected at Brooklyn by a new organization, termed the H. A. Metz Laboratories, Inc., and the requisite technical staff was secured.

After overcoming the inevitable difficulties attendant upon the establishment of an exceptionally delicate and complicated manufacturing process, the new company is now in a position to supply salvarsan in commercial quantities. It recently issued the following statement:

"Salvarsan is now being made in our new Brooklyn laboratories under the supervision of Dr. G. P. Metz, who was instructed in the process of manufacture at Hoechst, Germany. It corresponds in every detail to the standards set by the late Dr. Paul Ehrlich, and is the only product made by the processes used at the Hoechst works.

"As is well known, the slightest irregularity in the process of manufacture of salvarsan may cause the formation in it of toxic by-products. In order to protect the public and ourselves against the effects of any accidental irregularities in manufacture, we ascertain toxicologically whether or not each lot of salvarsan prepared by us is free from such toxic by-products. This knowledge is obtained for us by the head of the Department of Biological Chemistry in one of our leading university medical schools, who bears the same judicial attitude to our preparations that Prof. Ehrlich did to the standard German preparations, and who subjects our preparations to biological tests that he considers more rigorous and comprehensive than those adopted for this purpose by Prof. Ehrlich, himself.

We will market only such lots of salvarsan as have been thoroughly tested by this biological chemist and pronounced by him to be free from injurious by-products. The name of our biochemical collaborator will be given to any who may wish to consult us regarding the nature and results of his tests of our preparations.

"This American-made salvarsan will be sold to the medical profession direct, until local agencies have been satisfactorily established."

Antipyretic Stimulants

Albert D. Barr, of McHale, Arkansas (Amer. Pat. 1,235,278, of July 31, 1917) describes the preparation of a class of stimulating, antipyretic crystalline compounds, obtained by bringing into combination coal-tar antipyretics of the acetanilide type, with organic acids, such as citric acid, and vegetable alkaloids possessing stimulant properties.

The method is illustrated by the following example:

To 6600 grains of citric acid ($H_3C_6H_5O_7$) add about a pint of water and heat to the boiling point. To this solution is added 4460 grains of acetanilide ($C_6H_5NH.C_2H_3O$) or its equivalent and the compound thus formed is boiled for about thirty minutes.

To this is added 7000 grains of caffein ($C_8H_{10}N_4O_2$) and the mass is boiled for two and one-half hours, care being taken to add, from time to time, the water lost by evaporation.

At the end of this time the solution is placed over a water bath and evaporated until the compound weighs about 18,060 grains, at which time it has become a true chemical compound of thick, syrupy consistency. It is then set aside in a cool place, and allowed to crystallize for from three to six weeks. The result is a true chemical combination containing acetanilide, citric acid and caffein molecules ($C_6H_5NHC_2H_3O$, $H_3C_6H_5O_7$, $C_8H_{10}N_4O_2$) in the proportions of ten parts of acetanilide, 14.8 parts of citric acid and 15.7 parts of caffein. On analysis it yields 24.7 per cent. acetanilide; 36.5 per cent. citric acid; and 38.8 per cent. caffein. It dissolves in about its own weight of water and is slightly hygroscopic during warm weather. The medicinal adult dose is from five to twenty-five grains and it is advantageous in all pathological conditions where there is a rise of temperature above 100°.3 F.

Increased Cost of Perfumery.

There has been a notable increase in the cost of all the materials entering into the cost of manufacturing artificial perfumes during the past three years. The following quotations of pound prices for June, 1914 and 1917, show the effects of limited supplies:

	June, 1914	June, 1917
Amyl salicylate	$1.28	$2.50
Benzaldehyde	.50	4.50
Oil of bitter almonds	4.00	12.50
Benzyl benzoate	.80	10.00
Phenyl-ethylic alcohol	10.00	54.00
Phenyl-acetic aldehyde	20.00	60.00

New Arseno-Phosphorus Compounds.

A new series of arseno-phosphorus compounds, presumably for therapeutic use, can be obtained from amino-phenylarsinic acid, by treatment with phosphorus oxychloride, according to the recent patent of A. Mouneyrat, of Paris, France (Amer. Pat. 1,232,373, of July 3, 1917). These compounds form yellowish powders and are soluble in dilute solutions of sodium carbonate.

MISCELLANEOUS

Manufacture of Benzyl Chloride.

The industrial production of benzyl chloride, $C_6H_5.CH_2Cl$, has never been perfected so as to result in a yield approaching at all the theoretical figures. The customary operation is to conduct chlorine upon the surface of boiling toluene, which absorbs it rapidly, until the toluene used shows an increase in weight of 38 per cent. The product is washed with water, and is then separated by fractional distillation from unaltered toluene, and from benzylidene dichloride, $C_6H_5.CHCl_2$, and benzotrichloride, $C_6H_5.CCl_3$, both of which are formed simultaneously and in considerable amount.

It is difficult to secure commercial benzyl chloride of any high degree of purity. The three substances above mentioned, and often various chloro-toluenes, are present in varying quantities in almost all cases.

Considerable interest is attached to the process recently patented by James B. Conant of Cambridge, Mass., and assigned to the Semet-Solvay Co. (Amer. Pat. 1,233,986, of July 17, 1917), in which benzyl chloride is produced by the formation of nascent chlorine in toluene.

The method is described as follows: The toluene to be chlorinated is placed in any suitable container provided with a stirrer and cooling coil. Bleaching powder is then mixed with the toluene in the proportion of one part of bleaching powder to two parts of toluene. It should preferably contain thirty-five per cent (35%) or more of available chlorine. Sulfur dioxide gas or a mixture of sulfur dioxide gas and nitrogen is next introduced into the mixture by bubbling it in through pipes entering the bottom of the container. Instead of sulfur dioxide there may be used any gaseous acid or acid anhydrid. Considerable heat is evolved by the subsequent reaction but the temperature at which the toluene is kept is of no importance for the success of the reaction. A return condenser may be fitted to the apparatus to prevent any loss of toluene. When between .1 and .5 of a pound of sulfur dioxide per pound of bleaching powder has been introduced, the reaction is finished. The toluene and benzyl chloride are now distilled off by means of steam from the solid residue, the toluene coming over first. The last portion consisting of toluene and benzyl chloride may be separated by fractional distillation. The yield is about one pound of benzyl chloride from every three to six pounds of bleaching powder, depending largely upon the quality of the bleaching powder. The unchanged toluene is recovered and is used over again, while the solid residue, consisting largely of calcium sulfate, may be readily washed out of the apparatus and thrown away.

It is claimed that the process has the following advantages over the ordinary procedure, viz., the reaction is much faster, thus requiring a less bulky apparatus for a given output; it does not necessitate the keeping of toluene at its boiling point; it does not require the use of chlorine gas, which is a corrosive substance, thus making a much simpler apparatus possible; it produces none or a small amount of chlorotoluene; it produces only a trace of other chlorination products of toluene; no corrosive hydrochloric acid gas is given off in the reaction.

Theft of Dye Formulas.

The theft of dye formulas claimed to be worth several million dollars to the Martin Dyeing and Finishing Company, Bridgeton, N. J., led to the arrest, in Philadelphia, July 5, of Louis Hihn. The Martin company has been working on United States Government contracts, engaged in the dyeing and finishing of cloth for uniforms for the new National Army. After the dye formulas were stolen, the dye plant, it is said, was greatly hindered in its work.

New Benzol Plant.

One of the largest benzol-recovery plants in the country is in course of erection at Duluth by the Minnesota Steel Co. The cost is placed at $500,000. The plant will be in operation during the coming winter.

Mr. James J. Bajda, lately chief dye chemist for B. Heller and Co., has been appointed superintendent of the color works, now under construction by the Block Chemical Laboratories.

THE AMERICAN MANUFACTURE OF LABORATORY APPARATUS

By F. W. Shulenberger.*

Though Less Spectacular, the Achievements of American Manufacturers of Laboratory Apparatus in Duplicating Articles of German and Austrian Make Have Been Equal to Those of the Chemists Themselves. Now, Declares the Writer, Where There is a Crying Need for Some Piece of Apparatus, a Way Is Usually Found to Procure It.

IT is a truism to state that the important work of the world is made possible by the possession of apparatus. This applies especially to factories and even to the farmer. It applies in particular to great communal undertakings such as the building of a railroad, the digging of a canal, or the waging of a war. One of the prominent political parties recommends in its plank the securing possession of the machinery of production.

These same conditions apply with special force to the chemical laboratory. As new demands are made on the chemist, new apparatus must be constructed to meet the requirements. The chemist is compelled sometimes to wait months, or even years, for a special piece of apparatus, without which a given test cannot be performed. In many laboratories, certain very important tests are not attempted because the financial backing is not at hand to purchase the expensive apparatus required. In some cases important apparatus cannot be obtained, even if funds are available, as, for example, at the present time, the polariscope. When it is remembered that the center of every up-to-date university is the chemical laboratory building, and the heart of every large manufacturing plant is its testing laboratory—not to mention the various private, municipal, or government research and control laboratories—the importance of the field of chemical laboratory apparatus will be to some extent appreciated. One prominent American research professor spent two years constructing the apparatus required for a special course. At the end of that time he was called away. The apparatus, however, remained for his successor, and is pointed out as one of the wonders of that university.

Germany and Austria Supplied the World.

It is claimed that the greatest single impetus to the commercial life of Germany, before the war, came through the manufacture of chemical laboratory apparatus. At that time, Germany and Austria had practically a monopoly of this business. This monopoly was fostered in a remarkable degree by the duty-free regulations of the United States and other countries. The duty-free orders went practically as a unit to these countries. The orders amounted to many millions annually. What was much more important, however, was the impetus which they brought to every branch of industry. The best apparatus was retained for home use. The latest discoveries from all countries were made at once applicable to this special field. There was at all times a corps of workers available who were familiar with the most up-to-date methods. The university graduates were placed at once where they could get that intimate practical training, for the want of which our university courses have been in many cases little more than a farce.

At the outbreak of the war, the United States, like other countries, was importing the better grades of chemical laboratory apparatus and chemical reagents almost wholly from Germany and Austria. Fortunately, there were in most cases large stocks on hand, and the British government permitted special shipments for a year or more after the outbreak of hostilities. Then all importations from Germany automatically ceased, except a few incidental shipments, as for example, what was brought by the Deutschland. On account of lack of materials and of workers, as well as of increased home demand, shipments from England, Sweden, Holland and France—the other countries which had previously furnished certain forms of laboratory appartus—diminished almost to the vanishing point. A notable exception in the case of England was quantitative filter paper, which was developed especially to meet the new unusual conditions. Large quantities of this English paper were shipped to America and it is now in regular use here. Japanese ware, particularly Japanese porcelain ware, also began to appear on the American market. It has come in increasing quantities ever since.

American Manufacturers Have Not Been Idle.

The most surprising development however, has taken place here in our own country. Factories of various kinds have sprung up as if by magic. One factory is producing chemical laboratory glassware, claimed to be better than any heretofore made abroad. Three or four others are producing glassware almost as good. Practically the same conditions apply to porcelain ware, though here the competition of the Japanese ware is a very serious factor. The number of glassblowing establishments, as well as the number of men employed, has increased very greatly. All the ordinary glass blown articles, as for example, condensers, tubes, bulbs, etc., are now made practically as required. The same applies to volumetric ware such as pipettes, burettes, flasks, cylinders, also hydrometers, picnometers, and thermometers. There is still difficulty in securing as rapidly as required special volumetric ware which is able to meet the requirements of the Bureau of Standards, and very accurate thermometers, such as the Beckman. Conditions are, however, improving continuously in this respect.

---

*Sales Manager, Apparatus Department, Eimer & Amend, New York.

Silica ware, formerly manufactured only abroad, is now made in this country. Alundum ware was originated here. Its scope has been greatly increased. Zirkite ware is just being introduced, and is recommended where very high temperatures are encountered. Palau ware, the new substitute for Platinum ware, seems to be equally satisfactory for most purposes, and costs only half as much. The output of domestic filter paper has been very greatly increased, and a number of new grades have already been put on the market. The glass factories are now turning out, almost as required, moulded ware such as jars, special bottles, and also more complicated forms such as gas generators, aspirator bottles, separatory funnels, etc. At first there was a great dearth of chemical reagents and dyes. This led to a very thorough investigation of our tremendous organic resources, consisting especially of coal and oil. The residues which had previously been disposed of largely in a practically crude condition, were now treated to obtain more refined products. At present most of the chemical reagents and dyes formerly made abroad are made in this country, and the movement seems to be just beginning. This development has been so rapid that in many cases where three years ago there were only swamps or other unused grounds, there are today row after row of factories and laboratories employing many chemists producing a great variety of chemicals and dyes.

Universities Can Do Much.

The universities seem to be duplicating a movement which took place in Germany many years ago. Then, in response to the needs of the times, there grew up around the leading university centers—more particularly Jena, Leipsic, Berlin and Vienna—a group of workshops, many of which developed into great factories sending their products to every part of the world.

The great Zeiss factory, for example, at Jena, originally inspired by the genius of Professor Abbe, developed later into a great cooperative community which seemed to have uttered the last word with reference to exactness of workmanship and detailed investigations extending into the most hidden recesses.

Under the stress of the world struggle and the needs of our country, American universities are establishing workshops and founding factories. There is probably not a prominent university in this country which is not producing or preparing to produce one or more articles for which there is an urgent demand and for which there is at present no other source of supply. In one or two cases formal action has already been taken by the Board of Regeants looking forward to the establishment of one or more factories in direct connection with the university. This movement is as yet only beginning.

Problems Confronting Our Apparatus Makers.

As previously indicated, there are some forms of apparatus which have not yet been satisfactorily duplicated in this country. Possibly first amongst these is the polariscope, almost indispensable for sugar control work. The main difficulty here is the lacks of suitable prisms. At the recent meeting of the American Chemical Society, the weakness of this country in the production of optical glass of all kinds was emphasized. However, several glass factories are now devoting special attention to this problem with every prospect of encouraging results. The conditions for polariscopes apply also to spectroscopes, though to a less extent. In the case of colorimeters, this optical difficulty seems to have been practically overcome. Agate mortars are not on the market at present. This is due partly to lack of suitable material, partly to lack of skilled workmen. Glass retorts have not yet been made in this country, at least to any extent, mainly because the demand is very limited. The supplies of platinum are very low. The government is endeavoring to retain the platinum for chemical uses, and is discouraging its use for jewelry or photographic purposes.

Among distinctive American contributions may be mentioned the following:—

Alundum, Zirkite and Palau ware, already alluded to. Especially important is a line of apparatus for the exact control of temperatures. This includes apparatus automatically controlled, electrically heated for temperatures from Zero to 40° centrigrade, similar apparatus for temperatures to 70°C, also to 180°C, also to 260°C. It also include furnaces for temperatures up to 1000°C and 2000°C or over, along with exact control through pyrometers and rheostats. It includes also, at the same time, an exact control of gaseous pressure from practically absolute vacuum up to many atmospheres along the gauges and pumps of various kinds for controlling the pressure. The condition of humidity is similarly controlled. There are also stirrers operating at exact speed, etc. In general, the tendency is to standardize every possible external condition.

In line with this general tendency may be mentioned special apparatus intended to add hydrogen or some other gas to an existing molecule, thus radically changing the material, also apparatus intended to remove hydrogen or some other gas from an existing molecule, thus again radically changing the material. By the first process, expensive oils, etc., are built up from cheaper grades. By the second process, crude natural gas, for example, is transformed to benzole, which is the basis of so many products.

Even more important and significant is the work which is being done in connection with colloids. The field is there very large; the operations involved are diverse, and the apparatus required is in many cases complicated. The early work in this field was done mainly abroad, much of it in connection with the ultra microscope. This modification of the microscope has not yet been put on the market from an American factory but probably will be in the near future. Other apparatus of value in testing colloids is a special viscosimeter, special electro analysis apparatus, etc. A line of new apparatus is just now being prepared to show crystallization, distillation, and evaporation in connection with colloids. The constant temperature and constant pressure apparatus is also of great importance in this connection.

It will probably have become clear that as new discoveries are made new apparatus is required. Usually the discovery and the invention of the apparatus go hand in hand; afterwards the apparatus is in many cases made more perfect. At present, owing to the tremendous exertions of American chemists and inventors, the difficult situation is fairly well cared for. Prices are high, but home production tends to increase so that normally prices would go down. The grade is being continually improved and where there is a crying need for some piece of apparatus a way is usually found to procure it.

NEW PUBLICATIONS OF THE BUREAU OF MINES.

(List 50.)

Coal-mine fatalities in the United States, 1916, compiled by A. H. Fay. 1917. 42 pp.

BULLETINS.

Bulletin 119. Analyses of coals purchased by the Government during the fiscal years 1908-1915, by G. S. Pope. 1916. 118 pp.

Bulletin 143. Abstracts of current decisions on mines and mining reported from May to August, 1916, by J. W. Thompson. 1917. 72 pp.

TECHNICAL PAPERS.

Technical Paper 87. Methods of testing natural gas for gasoline content, by G. A. Burrell and G. W. Jones. 1916. 26 pp., 7 figs.

Technical Paper 106. Asphyxiation from blast-furnace gas, by F. H. Willcox. 1916. 69 pp., 8 pls., 11 figs.

Technical Paper 165. Quarry accidents in the United States during the calendar year 1915, compiled by A. H. Fay. 1917. 77 pp., 1 pl.

Technical Paper 168. Metal-mine accidents in the United States during the calendar year 1915, compiled by A. H. Fay. 1917. 114 pp., 2 figs.

(List 51.)

BULLETIN.

Bulletin 124. Sandstone quarrying in the United States, by Oliver Bowles. 1917. 143 pp., 6 pls., 19 figs.

TECHNICAL PAPERS.

Technical Paper 82. Oxygen mine-rescue apparatus and physiological effects on users, by Yandell Henderson and James W. Paul. 1917. 106 pp., 5 pls., 6 figs.

Technical Paper 135. Bibliography of recent literature on flotation of ores, January to June, 1916, compiled by D. A. Lyon, O. C. Ralston, F. B. Laney, and R. S. Lewis. 1917. 20 pp.

Technical Paper 140. The primary volatile products of the carbonization of coal, by G. B. Taylor and H. C. Porter. 1916. 59 pp., 1 pl., 25 figs.

Technical Paper 143. The ores of copper, lead, gold, and silver, by C. H. Fulton. 1916. 45 pp.

Technical Paper 160. The determination of nitrogen in substances used in explosives, by W. C. Cope and G. B. Taylor. 1917. 46 pp., 1 pl., 4 figs.

Technical Paper 166. Motor gasoline; properties, laboratory tests, and practical specifications, by E. W. Dean. 1917. 27 pp.

Note.---Only a limited supply of these publications is available for free distribution, and applicants are asked to co-operate in insuring an equitable distribution by selecting publications that are of especial interest. Requests for all papers can not be granted. Publications should be ordered by number and title. Applications should be addressed to the Director of the Bureau of Mines, Washington, D. C.

Ultra Violet Light

By Carleton Ellis and A. A. Wells.

The publishers of the Chemical Engineer regret to announce that owing to an accident the manuscript of Part VII of the article, "Ultra Violet Light: Its Application in Chemical Arts," by Carleton Ellis and A. A. Wells, was not available for publication in this issue. The installment referred to continues the discussion of the sterilization of liquids by means of ultra violet rays. To readers who have been following this article every month are offered apologies and the assurance that it will make its appearance in the October issue.—Ed.

Swiss Manufacture of Coal-Tar Products.

The manufacture of coal-tar dyes and medicinals in Switzerland is confined chiefly to the city of Basel. The four large companies in that city engaged in this branch report profits far in excess of any sums hitherto recorded. Thus the well-known Sandoz Color Works paid at the close of 1916 dividends of 25 per cent. and in addition a bonus of $200 per share. This was after granting a bonus of $80,000 to the working staff and setting aside ample sums for various funds.

These conditions are causing alarm in German manufacturing circles, especially when taken in connection with the existing embargo on the exportation of nearly all chemical and pharmaceutical products from the Empire. A German trade journal expresses openly the fear that "the world's markets have found new sources of chemical products, and will learn to do without those of German origin if exportation is not made easier as quick as possible."

CONTENTS, SEPTEMBER, 1917

Coal-Tar Chemistry 241
Edited by Thomas H. Norton, Ph.D., Sc.D.
Under which is included:

EDITORIALS:

The Purity and Strength of American Artificial Colors 241
Death of Adolph von Baeyer 242
Co-Operation in Research 243
Artificial Phenol 244
Women and Dyestuffs 244
Swift Expansion of the American Manufacture of Coal-Tar Colors 245
The Swiss Color Industry 245
The Reliability of American Colors 246
The New Location of the National Aniline and Chemical Co. 246

COAL-TAR CRUDES:

The Manufacture of Anthracene 247
Some Sources of Benzene and Toluene for High Explosives 249
T. F. E. Rhead.
The Recovery of Toluene from Illuminating Gas 250
The German Coal-tar and Explosive Industries 254
Estimation of Benzol in Gas 254
Coal-tar Crudes in Australia 254
The British Supply of Coal Tar 254

COAL-TAR INTERMEDIATES:

Sulfonating Kettles 254
Explosions of Picric Acid 257
T. Sington.
Conflagrations in Coal-Tar Chemical Plants 258
Manufacture of Benzene Sulfonic Acid 258
A New and Sensitive Indicator 258

ARTIFICIAL COLORS:

A Series of New Ortho-Oxy-Azo Dyestuffs Containing Copper 259
Growth of the American Dyestuff Industry. 260
Standards of Dye Strength in England 263
The Dyeing of the New Standard Khaki in England 264
C. M. Whittaker, B.Sc.
The Bayer & Co. Works at Rensselaer 265
Colors for Army Uniforms 265
The Combination of Leading German Manufacturers of Artificial Colors 266
Reserve Stocks of Artificial Dyes in China .. 267

NATURAL DYES:

The Manufacture of Archil Extract in the United States 268
Views of Archil Industry at Magdalena Bay 269
Autumnal Foliage as a Source of Dye 270

SYNTHETIC DRUGS AND PERFUMES; PHOTOGRAPHIC DEVELOPERS:

Salvarsan of Domestic Make 271
Antipyretic Stimulants 272
Increased Cost of Perfumery 272
New Arseno-Phosphorus Compounds 272

MISCELLANEOUS:

Manufacture of Benzyl Chloride 272
Theft of Dye Formulas 273
New Benzol Plant 273

CURRENT WHOLESALE PRICES OF COAL-TAR PRODUCTS:

Crudes, Intermediates and Explosives, Synthetic, Medicinals, Flavors and Perfumes, Photographic Developers, Artificial Colors 273
Natural Dyestuffs, Dyewoods and Raw Materials, Extracts, Dyeing Accessories 274
Imports and Exports of Coal-tar Products and Natural Dyestuffs 274
The American Manufacture of Laboratory Apparatus 275
F. W. Shulenberger.

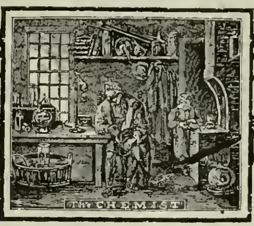
CHEMICAL INVESTIGATION
EFFICIENCY & CONTROL

CONDUCTED BY CHARLES B. DAVIS, F.C.S.



ALL classes of work covered by the following subjects will be done for readers of "The Chemical Engineer" through this department by Mr. Davis: Special research of every description; analysis and reproduction of any commercial product; prevention of waste and utilization of by-products on the most economical basis; valuation of raw materials; food analysis, and disputed points in regard to adulteration, labeling, and the enforcement of pure food laws; bacteriological and enzymatic examinations, including fermentation tests, pure yeast cultures, beverages of all kinds; development of chemical inventions and industrial processes; examinations and advice on special machinery.

Inquiries of a minor character will be answered on this page, while major matters involving personal investigations, analyses, etc., will, if desired, be treated confidentially through the mails. All questions, materials for analysis, or letters leading to the opening of negotiations for special work will receive prompt attention if addressed to

CHARLES B. DAVIS,
Care of "The Chemical Engineer," 118 East 28th Street,
New York City.

P. A.—I note from the official letter you have just received from the patent office and which you have forwarded me that the first and third claims have been erased in accordance with my advice to you in the May issue. I am sending you by mail the full amendment to the patent, including three new claims. If these new claims are allowed, which I believe they will be, since they do not infringe any of the patent citations, I would strongly recommend that the patent be allowed to go to issue without further changes. The claims, as now drawn, fully cover the subject matter contained in the specification.

H. S. W.—The sample of oil from the insurance company was received on the fifteenth of last month. I find that when this oil is incorporated with wool it rapidly heats up in the manner complained of. On chemical analysis this oil is shown to consist of fatty acids and has a decidedly fishy odor. Its fish origin is further confirmed by the yield of insoluble bromides, which bromides, instead of melting to a clear liquid at 176 C gradually blackened and decomposed showing that the Hexabromides are not of linseed oil origin.

My full report with opinion and recommendations will be forwarded to the company by the end of this month.

A. A. T.—The French patent covering a process for producing "Motor Spirit for Internal Combustion Motor Engines" is carried out in the following manner:

The fraction of kerosene oil boiling up to about 220°C, which must be practically free from petroleum spirit, is forced through very narrow interstices at high pressure; the resulting product burns more rapidly than kerosene oil.

After you have concluded your experiments I shall call and take samples at different stages of your process and submit them to official burning tests in order to ascertain whether your product is superior to that of the French process and then render my report to the persons you mentioned.

T. W. L. I find on analysis that the dyestuff contained in your wool sample was produced by the following method:

5.0 grams of hydrochloric acid (sp. grf. 1.143.
5.0 grams of analin.
1.0 grams of p-nitranilin.
2.0 grams of nitrobenzene.
0.03 grams of ammonium molybdate.

Boil these ingredients together and raise the temperature to 220C, when the mass will form a paste. Now dissolve this paste in hot water and precipitate the dye by the addition of soda. In dyeing with this, an acetic acid bath is used.

E. S. E. From the chemical analysis of the artificial stone you forwarded this month, the working formula for its reproduction is as follows:

The materials are crushed and ground and 4.0 per cent. binding material in the form of quartz is added. Now incorporate sufficient water to form a stiff paste and press hydraulically into your desired shapes and burn in the electric furnace.

W. T. Your desire for a process of canning requiring no heating or pasteurization and producing products free from antiseptics is being looked into. I understand also that no sugar is to be used. The fee charged for this class of work will be commensurate with the time consumed in the investigation. I have not the slightest doubt that such a process can be devised.

Charles B. Davis.

Those whose inquiries to this department have not as yet received attention must bear in mind that unless replies by mail ar specifically requested, communications can only be considered in the order of their receipt.—Editor.

FOREIGN TRADE OPPORTUNITIES

These Opportunities for Foreign Business Relations Are Made Public by the Bureau of Foreign and Domestic Commerce, of the Department of Commerce, Washington, D. C. Names, Addresses and Details May Be Obtained from the Bureau or Any of Its Branches. Refer to the Number of Each Opportunity and Place Inquiries for More Than One on Separate Sheets.

Celluloid Articles.

25053.—A man in France desires to purchase, or to secure an agency for celluloid articles of all kinds, linen, silk, and cotton hosiery. He will guarantee in advance large purchases of goods each year. Correspondence should be in French. Reference.

Formaldehyde, Tannic Acids, Etc.

24800—A firm in England wishes to buy cream of tartar substitutes, formaldehyde, pharmaceutical products, tannic acids, etc. Samples and complete analysis should be submitted. Payment will be made by cash against documents through New York bankers. Quotations should be made c. i. f. or f. o. b. any port. References.

Carbon Balls.

24332—A firm in New Zealand is in the market for carbon balls. Quotations should be made f. o. b. American port. Payment will be made through a branch office in London. Correspondence may be in English. Reference.

Chemical Products.

24826—A company in Italy wishes to buy starch, dextrine, resin, chemical products, etc. A complete list of the commodities desired may be had on application of the Bureau or its district offices. Reference.

Paints, Oils and Explosives.

25020.—A man in Bolivia who has been very successful as a general importer and exporter, wishes to secure agencies for sheet steel, corrugated and flat, galvanized, etc., wire nails, steel rails and structural steel, window and plate glass, flour, lumber, canned salmon and other canned foods, Siam and India rice, cement, paints and oils, and explosives. He prefers to deal direct with manufacturers.

DISTILLATES

News Notes of Chemical and Allied Industries

Chemicals.

The M. B. Manufacturing Corporation, Manhattan, has been incorporated under the laws of New York to manufacture and deal in chemicals, by N. Lazarus, A. Phillippe and A. Romero, 5,000 Broadway, with 100 shares of preferred stock at $100 each and an active capital of $5,500.

Chemicals and Drugs.

The Lippincott Chemical Co., Inc., Manhattan, has been incorporated under the laws of New York with a capital of $25,000 to deal in chemicals and drugs, by W. A. Lippincott, B. Berkow and J. F. Russell, Jr., 43 Cedar street, New York City.

Chemical Compounds and Dyestuffs.

With an active capital of $5,000 and 1,000 shares of common stock, no par value, the Clement Synthetic Gas & Chemical Company, Inc., Manhattan, has been incorporated under the laws of New York to deal in chemical compounds, dyestuffs, airplanes and automobiles. L. Clement, R. T. Grogan and H. Boes, 119 East 88th street, New York City, are the incorporators.

Nitrogen Fixation Corporation.

With a capital of $1,000,000, the Nitrogen Fixation Corporation, Manhattan, has been incorporated under the laws of New York, to manufacture cyanogen compounds and carry on a general chemical business. The incorporators are J. F. A. Comstedt, J. R. Rubin and S. M. Weil, 34 Pine street, New York City.

Analytical and Consulting Chemists.

Ossa Sowers, Inc., analytical and consulting chemists, has been incorporated under the laws of New York to operate laboratories in Manhattan with a capital of $5,000. The incorporators are J. P. Ross, J. Jacobson and O. Sowers, 9 East 9th street, New York City.

Drugs and Chemicals.

Brooklyn Standard Laboratory, Brooklyn, N. Y., has been incorporated under the laws of that state to manufacture chemicals, drugs, supplies and general merchandise. The capital is $10,000 and the incorporators are P. W. Schumacher, P. F. Lahm and L. Schopfer, 213 Cornelia street, Brooklyn.

Single Copies, 25c.

Statement of the Ownership, Management, etc., Required by the Act of Congress of August 24, 1912,

Of the Chemical Engineer, published monthly at New York, N. Y., for October 1st, 1917.

County of New York, State of New York, ss.

Before me, a Notary Public in and for the state and county aforesaid, personally appeared Robert H. McCready, who, having been duly sworn according to law, deposes and says that he is the Business Manager of the Chemical Engineer, and that the following is, to the best of his knowledge and belief, a true statement of the ownership, management (and if a daily paper, the circulation), etc., of the aforesaid publication for the date shown in the above caption, required by the Act of August 24, 1912, embodied in Section 443, Postal Laws and Regulations, printed on the reverse of this form, to wit:

1. That the names and addresses of the publisher, editor, managing editor, and business managers are: Publisher, McCready Publishing Co., 118 East 28th St., N. Y.; editors, Thos. H. Norton, 118 East 28th St., N. Y.; L. T. Clark, 118 East 28th St., N. Y.; managing editor, none; business manager, R. H. McCready, 118 East 28th St., N. Y.

2. That the owners are: C. J. O'Brien, 22 North William St., N. Y.

3. That the known bondholders, mortgagees, and other security holders owning or holding 1 per cent. or more of total amount of bonds, mortgages, or other securities are: None.

4. That the two paragraphs next above, giving the names of the owners, stockholders, and security holders, if any, contain not only the list of stockholders and security holders as they appear upon the books of the company, but also, in cases where the stockholder or security holder appears upon the books of the company as trustee or in any other fiduciary relation, the name of the person or corporation for whom such trustee is acting is given; also that the said two paragraphs contain statements embracing affiant's full knowledge and belief as to the circumstances and conditions under which stockholders and security holders who do not appear upon the books of the company as trustees hold stock and securities in a capacity other than that of a bona fide owner; and this affiant has no reason to believe that any other person, association, or corporation has any interest direct or indirect in the said stock, bonds, or other securities than as so stated by him. ROBERT H. McCREADY.

Sworn to and subscribed before me this 21st day of September, 1917.
FREDERICK PFISTER.
(My commission expires March 30, 1919.)

War Profits of Chemical Corporations.

In the taxation of the extra "war profits" earned by American industrial corporations, it is quite evident that chemical companies, and especially those closely connected with the manufacture of coal-tar products, will contribute a leading share. The following table shows the net earnings, for the past three years, of the leading companies in this category:

Companies.	1916.	1915.	1914.
Atlas Powder Co....	$2,639,790	$1,671,762	$294,150
Barret Co...........	4,247,858	2,482,236	1,280,476
du Pont de Nemours	82,013,020	57,257,308	4,831,793
General Chemical Co.	12,286,826	5,958,746	2,857,898
Grasselli Chemical Co.	6,760,669	4,859,000	1,080,000
Hercules Powder Co.	16,688,873	4,886,102	1,247,255

THE SIGNIFICANCE OF THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES

By Thomas H. Norton, Ph. D., Sc. D.

Wholly Apart from Its Appeal to the Eye, but of Vastly Greater Importance, Was the Undercurrent of Intense Seriousness which Sooner or Later Inevitably Forced Itself Upon Visitors to the National Exposition of Chemical Industries Held in New York. In the Following Analysis of the Event, the Writer Interprets Its Psychological as Well as Its Commercial Significance, and Also Gives a Thorough Review of the Exhibits and Addresses.

The Third National Exposition of Our Country's Chemical Industries, held on the week beginning September 24, at the Grand Central Palace in New York City, was, in every way, a notable event.

The first exposition, in September, 1915, was largely tentative, but proved to be a distinct success. When its successor was held in 1916 the number of exhibits was doubled and the attendance largely increased.

In 1917, despite the fact that we are fairly embarked upon a war, prospectively the greatest in our national history, the exposition proved to be a pronounced advance upon that of the preceding year. The exhibitors numbered 325 and the space occupied was triple that of 1915, three floors of the vast building being covered by their displays.

The number of admissions was over 100,000. It was estimated that about 25,000 chemists, consumers of chemicals, producers of chemicals and manufacturers of the accessories required by the latter were brought together during the exposition.

It was eminently educative, although practical business purposes were the chief incentive in the case of most exhibitors. As a rule what they displayed in their booths was so arranged and labeled or explained by competent attendants that the layman could easily grasp the economic importance of the wares shown. Their origin, their relation to one another, their uses were all brought out clearly and in most instances attractively and tastefully.

There was, however, an almost complete absence of the spectacular. An undertone of great seriousness was evident. Not only the topics of conversation among the throngs in attendance, but the character of the exhibits, and the dominating note in the various addresses and lectures all revealed a consciousness that we have entered upon an historic epoch destined to test to the uttermost the entire fabric of American chemistry as well as American ingenuity, adaptation and inventive skill.

There was an inspiring conviction that the chemists of our nation are fully competent to deal with the manifold problems accompanying this greatest of the world's wars, in which we are now about to play a leading part, possibly the decisive rôle. It is pre-eminently a war of engineers and chemists. Can American chemists show themselves fully equal to the chemists of Europe in evolving methods of offense and means of defense?

The booths of the exposition contained the answer. They revealed to the eye the wonderful accomplishments of the past three years. They showed how swiftly and how effectively it has been possible to create on American soil the manufacture of a multitude of products, for which a few months ago we were entirely dependent upon European sources. The eye rested frequently upon the imposing mechanical appliances requisite for the life of new-born chemical industries.

Leaders of American chemistry portrayed eloquently how we have become a giant purveyor of powerful explosives; how we are dealing with a multitude of problems intimately associated with war in the air and beneath the ocean's waves as well as in the trenches.

The intelligent and patriotic citizen could not leave the halls of the exposition without the profound convicition that our chemists form a first line of national defense, that without their wholehearted, far-reaching co-operation the power of the legions we send across the Atlantic would be sadly crippled.

In analyzing the exposition more in detail there was general recognition of the leading rôle played by the coal-tar chemical industry. Its products were shown in abundance, upon every hand. They lend themselves admirably to effective displays for the eye, and they revealed in a concrete form the marvelous creation during a few months of what will constitute permanent factors in our economic structure.

Next in interest came the varied mechanical devices provided for the chemist to accomplish his wonders. There is little doubt but that the confidence and assurance felt by our chemists in facing the numerous problems of today and of the morrow, is vastly reinforced by the realization of the equal ability of our engineers to furnish the most varied equipment for their needs.

Closely associated in this connection was the evidence of the success recently following American enterprise in making from American materials the many diverse articles in glass and porcelain needed constantly by the chemist, but obtainable hitherto only from Germany. In this category falls also the fine quality of optical glass now made in the United States.

All in all the exposition was thoroughly worthy of the nation's swiftly expanding industry, in which so many millions have been invested these past three years. It was eminently satisfactory to the economist, revealing the degree to which we are emancipating ourselves from foreign dependence. Finally it was inspiring to the intelligent and patriotic citizen, outlining clearly one of the potent factors for success in the war before us.

THE EXHIBITS.

It is impossible to present more than a very cursory mention of the many exhibits of distinct value to those interested in coal-tar chemistry.

To a certain extent something of value, something suggestive and helpful might be found in nearly every display. This was especially true of the many exhibits of machinery and other accessories required in chemical plants.

It seems, however, desirable to group together those exhibits which revealed in a very striking manner the present status of coal-tar chemistry in the arts, and the tremendous advance made during the past two or three years. Enough detail is furnished in connection with the name of each company exhibiting to give a fair idea of the extent and variety of its operations. The list includes all exhibitors engaged in the production of coal-tar crudes, in the refining of the crude products, in the transformation of such crudes into intermediates and in the manufacture from such intermediates of finished dyestuffs, medicinals and other allied substances. It includes further the exhibits of natural dyes and of the leading firms supplying the special mechanical equipment of the plants devoted to coal-tar chemicals.

In their entirety these exhibits formed the most striking feature of the exposition and attracted general attention.

The Barrett Co., New York.

The exhibit of this company was one of the most attractive and instructive in the whole exposition, showing the great range and variety of the current commercial products isolated from coal-tar. The list of these crude and refined substances is given in full in order to convey an adequate idea of the extent to which differentiation has been carried in the primary stage of the coal-tar chemical industry for the purpose of meeting a multitude of well-defined economic needs: Benzol, pure; benzol, 100%; benzol, 90%; benzol, 50%; benzol, straw color; toluol, pure; toluol, commercial; toluol, straw color; xylol, pure; xylol, commercial; solvent naphtha; crude solvent naphtha; hi-flash naphtha; crude heavy solvent naphtha; No. 10 naphtha; heavy naphtha; pyridine, denaturing; pyridine, commercial; heavy solvent oil; shingle stain oil; special heavy oil; special heavy oil, grade 2; neutral hydrocarbon oil; creosote oil; crude carbolic acid, in 8 grades; dip oil; phenol, U.S.P., natural; phenol, U.S.P., synthetic; cresol, U.S.P.; refined cresylic aid, No. 5; ortho-cresol; para-cresol; meta-cresol; xylenols; naphthalene, flake, small balls, large balls, crushed, powdered, granulated, rice, lump, one-ounce cakes, square tablets and round tablets; cryst alba; anthracene (crude) 25%; anthracene 40%; anthracene, 80%; carbazole; phenanthrene; pyxol; tarola X; special cresol compound; disinfecting powder; disinfectants, coefficients 2 to 20.

Quite recently the company has taken up the manufacture of various intermediates and medicinal compounds. The exhibits in this field were:

Paracumaron resin; para-amido-phenol; nitro-naphthalene; alpha-naphthylamine; resorcin, technical; resorcinol, U.S.P.; salicylic acid, U.S.P.; sodium salicylate, U.S.P.; methyl salicylate, U.S.P.; salol, U.S.P.; salicylimide.

In the 30 different plants of the company over 200 distinct chemical products are now currently manufactured. Great quantities of benzene and toluene are furnished under contract to the Allied governments to use in making munitions.

The Barrett Company has been the chief organization in this country to perfect the methods of separating the different constituents of coal-tar, and to popularize the use of the varied products in almost numberless directions. It is to the efforts of this company, extending back for years, that our synthetic chemists found it possible since 1914 to secure promptly large amounts of coal-tar crudes, refined to the requisite state of purity, as they laid the foundations for an American dyestuff industry, and for the production of numerous medicinals. Synthetic phenol was made by the Barrett Company some 10 years ago, although no effort was then attempted to place it regularly upon the market.

An impressive feature of the exhibit was a large wall chart showing the genealogical derivation of the leading products resulting from the destructive distillation of coal. Samples of these products, in vials of uniform size, accompanied the various names on the chart, which numbered slightly over 200. The realistic diagram is of pronounced educational value, and could most helpfully be employed in every school of science specializing in coal-tar chemistry.

The American Coal and By-Products Coke Co., Chicago.

This company had an interesting exhibit of the plans and materials used in the construction of the Roberts flueless coke oven. The importance of this oven, as permitting a vastly enlarged utilization of numerous deposits of bituminous coal, hitherto regarded as valueless for coking purposes, has attracted widespread attention. As the only by-product coke oven of purely American origin it promises to solve urgent problems connected with the satisfactory and economic distillation of many forms of soft coal, now untouched for this purpose, and also of the enormous deposits of lignite in our Western States. The company displayed a tasteful array of coal-tar crudes and their derivatives coming from the plant at Canal Dover, O.

The H. Koppers Co., Pittsburgh, Pa.

An instructive exhibit was made of the details of construction of the coke ovens installed by this company at various points, and contributing largely to our current supply of coal-tar crudes. The immediate products of coking were shown in a well arranged set of samples.

The United Gas Improvement Co., Philadelphia.

An extensive series of refined coal-tar crudes was shown by this company, which manufactures on a large scale all of the products obtained directly from tar. The pure compounds included benzene, toluene, xylene and naphthalene. The manufacture from the latter of phthalic anhydride has recently been installed and a daily production of 200 lbs. has been attained. Other exhibits were crude phenol, solvent naphthas, heavy naphthas, dead oil, creosote oil, paving and roofing pitches, road compounds, etc.

The Semet-Solvay Co., Syracuse, N. Y.

One of the most attractive features of the exposition was the finely arranged display of the company's products obtained from coal-tar. These included the hydrocarbons and the high explosives picric acid and trinitro-toluene derived from them; phenol and such derivatives as salicylic acid, methyl salicylate, acetylsalicylic acid, etc. The relationship of the various compounds to coal was shown on several tables holding sample bottles with arrows indicating the different changes as the result of chemical change. The whole exhibit was unusually instructive, and illustrated the growing tendency among manufacturers to present the basic facts in their processes so clearly and simply that they may easily be grasped by the non-scientific mind.

This organization has contributed much to the rapid expansion of the coal-tar chemical industry by its intelligent handling of the crude material controlled by it in large amounts in connection with the establishment of Semet-Solvay by-product coke ovens. The company now operates twenty-one plants under its system and claims to be the largest individual producer in the world of coal distillation products. It has not attempted to manufacture a great variety of compounds, but a limited number have been produced upon a very extensixe scale. Sulfur black is the only dyestuff which the company has manufactured.

The National Aniline & Chemical Co., Inc., New York.

The exhibit of this company attracted general attention from the fact that it is the largest single factor in the American coal tar color industry. It represents a consolidation of various interests, producers of coal-tar crudes, of intermediates, of synthetic colors, and of the chemicals required in the various stages of manufacture, which will enable it to develop along numerous special lines at a minimum of cost of production. A few months ago it was organized by the merging together of the following companies: Schoellkopf Aniline & Chemical Works, Inc., Buffalo; W. Beckers Aniline & Chemical Works, Inc., Brooklyn; National Aniline & Chemical Co., New York; Benzol Products Co., Marcus Hook, Pa.; Standard Aniline Products, Inc., Wappingers' Falls, N. Y.; and also certain plants and properties of the General Chemical Co., the Barrett Co. and the Semet-Solvay Co.

The extensive exhibit included a number of different categories and covered nearly the whole range of coal-tar products. They are given in detail, as illustrating in a striking degree the wide diversity of output of our leading producer of artificial dyes and its lack of dependence upon outside sources for the materials employed.

Coal-tar chemicals, used in textile or other industries: Aniline oil, aniline salt, beta-naphthol, cresol, phenol, diphenylamine, dimethyl-aniline, hydroquinone, meta-phenylene diamine, meta-toluylene diamine, naphthalene, nitro-benzene, paranitraniline, paramidophenol, para-phenylene diamine, phenol, phenyl ethyl alcohol, resorcin, sodium benzoate, thiocarbaniline, thiocarbtoluide, thiocarbxylide, benzaldehyde, benzyl acetate, benzyl benzoate, benzoic acid.

Intermediates, used chiefly in making synthetic dyes: Amido-salicylic acid, benzidine, chromotropic acid, dinitro-benzene, dinitro-toluene, G salt, H acid, Koch acid, metanilic acid, N W acid, naphthol1sulphonic acid (1:5), ortho-toluidine, phenyl-hydrazine-sulphonic acid, paramido-acetanilide, phenyl acid, picramic acid, pseudo-cumidine, R salt, sulphanilic acid, Schaeffer salt, xylidine.

Direct aniline colors, for cotton, union goods, etc.: Erie black GXOO, Niagara blue 2B, Niagara dark blue 3R, Niagara blue D B, ammaco direct blue 3B, Erie brown C, Erie brown G R, direct brown T, Erie green W T, ammaco direct green W B, Erie green M T, Erie orange 2R, benzo purpurine 4B W, Congo red 4B, Niagara garnet R, ammaco primuline W B, Niagara violet B W, Niagara fast yellow F, Niagara yellow K M, ammaco chloramine yellow W B, ammaco delta red 2B.

Sulphur colors, for cotton, fast to washing, cross-dyeing, etc.: Sulphur black F conc paste, sulphur black sap powder, sulphur blue paste, sulphur blue sap, sulphur direct navy blue, sulphur brown 2G, sulphur brown sap, sulphur brown W F, sulphur brown LY conc, sulphur green sap, sulphur yellow B W, sulphur khaki, all shades.

Acid colors, for wool, silk, leather, lake making, etc.: Buffalo black N B R, Buffalo black 10B, Buffalo black 8B, Buffalo black 3G, Buffalo black R B, ammaco acid black T R, Buffalo black A K, acid black 4 A B, Buffalo fast blue R, Buffalo cyanone 3R, induline, resorcine brown, fast brown, ammaco acid green

L, orange A conc, orange S conc, orange 2G crystals, brilliant scarlet 3R, xylidine scarlet, fast red S conc, scarlet B R, azo rubine extra, Buffalo fast crimson R, azo Bordeaux, Buffalo fast fuchsine D, Buffalo fast fuchsine G, Buffalo fast fuchsine R, Buffalo fast fuchsine 6B, wool red 40F, cloth red G, cloth red R, croceine scarlet moo, lanacyl violet M, acid violet, Buffalo violet 4B, Buffalo fast violet B, wool yellow ex conc, azo yellow A 5W, metanil yellow 1955.

Basic colors, for leather, paper, lake making, cotton printing, etc.: Brush blacks, methylene blue B S conc, ammaco basic navy blue D A conc, Bismarck brown Y ex, Bismarck brown 53, ammaco Victoria green W B, chrysoidine Y ex, chrysoidine 3R, safranine A, ammaco safranine B L, methyl violet.

Chrome colors, for wool, fast to light, fulling, etc.: Buffalo chrome black 2B N, ammaco chrome black B N, alizarol black 3G, alizarine blue G, alizarine dark blue G N, alizarine dark blue R B N, alizarine bright blue 3R Y N, serichrome blue R, alizarol brown B, alizarol brown R B, serichrome green B, Buffalo chrome green C B, ammaco alizarine orange W B, ammaco alizarine yellow 331, alizarol yellow 3G.

Certified colors, for food products, confectionery, etc.: Amaranth 107, ponceau 3R 56, orange I 85, tartrazine 94, sodium indigo disulphonate 692, Ceylon red, Sultan red, Burmah red, Coralline red, Rajah red, raspberry red, strawberry red, Brazil brown, Caracas brown, Maracaibo brown, deep chocolate, yellow color, egg shade; Tokio orange, Tangier orange.

Miscellaneous colors, Nigrosines, water and spirit soluble: Oil black, chrysoidine base, Victoria green base, oil colors, fur black, fur brown.

Most of the colors were accompanied by handsome specimens of their use on different textiles, leather, etc.

The company has branch agencies in twelve cities and is steadily increasing the number of its tinctorial products. It is in an admirable position to present a bold face to foreign competition when the time arrives in the early future.

It is not easy for the layman, or even for the average chemist, to realize adequately the full extent to which our textile and many allied industries are indebted to the above organization and its component parts for diminishing by wonderful energy and skillful utilization of available materials the pinch of our dyestuff famine.

The Central Dyestuff & Chemical Co., Newark, N. J.

This company has been an important factor in laying the foundation of the American artificial color industry, its origin dating back to 1898. It has specialized in azo dyes and its products have been of great value in meeting the pressing demands of the past three years. The current output was displayed in a most attractive manner and included the following colors: Fast red, orange G and Y, erythrine, benzopurpurine B, naphthol blue, scarlet 2R, methyl violet 3B, chrysoidine X, diamine blue 2B, azo rubine, claret red R B, Bismarck brown R and Y, amaranth, chrome black, fast acid red 6B G, amido black B, wool orange G, wool scarlet 4R, Bordeaux, lake violet, lake scarlet, lake brown, lake orange, roccelline, methylene blue, wool claret, induline, various nigrosines and numerous oil colors. The company is one of the leading producers of b-naphthol and exhibited this compound, as well as a-naphthol and a-naphthylamine. Sample dyeings of all the colors were present in abundance and the entire display gave admirable evidence of the energetic manner in which the older coal-tar color firms are extending the range of their operations.

Consolidated Color and Chemical Co., Newark, N. J.

This company manufactured a few colors on a relatively small scale before the war. It has not increased greatly the variety of its output, but is producing very large quantities. It displayed methylene blue, methyl orange, chromotrope, alizarin brown, acid yellow, cotton yellow, chrome black, chrome blue, chrome yellow, Victoria leather oil and a variety of sulfur dyes. Sample dyeings accompanied each color.

Marden, Orth & Hastings Corporation, New York.

This firm had a very tastefully arranged display of the products made in its seven factories, which included a large number of general chemicals, especially such as are required by dyers and tanners. The firm has branched out extensively into coal-tar products and showed the following:

Coal-tar Crudes and Intermediates.

Aniline oil, aniline salt, benzidine base, benzidine sulphate, benzol, beta-naphthol, chlor-benzol, dichlorbenzol, dimethylaniline, dinitro-naphthalene, dinitrophenol, hydroquinone, naphthalene, naphthionic acid, nitro-benzol, nitro-toluol, paranitraniline, phenol, picric acid, salicylic acid, salol, sulphanilic acid, toluidine mixture, toluol, xylidine, ortho-toluidine, para-toluidine, sodium naphthionate, sodium salicylate, sodium sulphanilate.

Acid Colors.

Acid black, acid blue, acid green, acid red, fast; croceine scarlet, orange No. 2, metanil yellow, acid yellow, azo orange.

Basic Colors.

Bismarck brown Y, chrysoidine Y, malachite green, methylene blue, methyl violet, nigrosine blue (water and spirit soluble), nigrosine jet (water and spirit soluble), Victoria blue S.

Chrome Colors.

Alizarin yellow R W, khaki No. 1 (for wool), anthracene acid brown G.

Direct Colors.

Direct black, Congo red, chrysamine G, direct blue, benzo brown G, benzo orange R.

Sulphur Colors.

Sulphur black, sulphur brown, sulphur yellow, sulphur blue, sulphur olive green.

Oil Soluble Colors.

Oil black, oil blue, oil brown, oil green, oil jet, oil orange, oil red III, oil red IV, oil scarlet, oil yellow, oil yellow D, oil yellow T.

The extraction of vegetable dyes is one of the company's specialties, and it introduced into general use aurantine paste and powder, obtained from our domestic osage orange. It exhibited the following:

Dyewood Extracts.

Logwood chips, logwood extract, hematine paste, hematine powder, hematine crystals, aurantine paste, aurantine powder, cutch, fustic extract, quercitron extract, sumac extract, cutch extract, hypernic extract, khaki No. 2 (for cotton).

The numerous samples, illustrating the use of the above colors, were grouped very effectively.

The Dow Chemical Co., Midland, Mich.

The exhibit of the many chemicals made by this company was extensive and impressive. The factory plant includes 260 buildings, and ranks among the most important of the country. Chief interest centered about the synthetic indigo, which is now being produced at the rate of nearly 2,000 pounds of 20% paste daily. The daily output will gradually be increased to 5,000 pounds. Much of the product is transformed regularly into dibromoindigo, which yields the most satisfactory results in cotton dyeing. Imports of the dibromo derivative from Europe were increasing prior to the war, and it is the feeling of the company that there is a large field for this compound. Prominent among the other coal-tar derivatives exhibited by the Dow Co., were synthetic phenol, salicylic acid, acetylsalicylic acid, methyl salicylate, ethyl salicylate, benzoic acid, sodium benzoate, sodium benzene-sulfonate, bromo-benzene, chloro-benzene, o-dichlorobenzene, p-dichloro-benzene, dinitro-phenol and tribromo-phenol. The acetic anhydride now produced by this company is of great importance to the synthetic color industry.

The Chemical Co. of America, New York.

The works of this company at Springfield, N. J., have become a leading center for the manufacture of coal-tar intermediates. Starting out early in 1915 with the production of aniline on a large scale, it has steadily enlarged the scope of its operations until it now furnishes most of the important intermediates. The following were exhibited: acetchlor-aniline, acet-toluide, amido-azo-toluol, aniline, aniline oil for red, anthranilic acid, Bayer's acid, benzaldehyde, benzidine base and sulphate, benzoyl chloride, benzyl chloride, chlor-aniline, chromotropic acid, diacetyl paramidophenol, dianisidine, diethylaniline, dimethylaniline, dinitrobenzol, dinitrochlorbenzol, dinitrophenol, dinitrotoluol, gamma acid, G salt, metanitraniline, metanitroparatoluidine, metaphenylenediamine, metatoluylenediaminel, monoethylaniline, naphtionic acid, nitro-benzol, nitrotoluol, ortho-nitro-chlor-benzol, ortho-nitro-paratoluidine, ortho-nitro-phenol, ortho-nitro-toluol, ortho-toluidine, para-amido-acetanilid, paramidophenol, paranitracetanilide, para-nitro-chlor- benzol, para-nitro-phenol, paranitrotoluol, paraphenylenediamine, para-toluidine, R salt, Schaffer's salt, sulphanilic acid, tetra-methyl-diphenylmethan, tolidine base and sulphate, toluidine, xylidine. The company has not yet taken up actively the manufacture of colors, but is making plans to enter this field at an early date.

The Seydel Manufacturing Co., Jersey City.

The company has undertaken the manufacture of benzoic acid upon a large scale, the annual output being 150 short tons. In its exhibit were the acid itself and the leading derivatives, sodium benzoate, b-naphthol benzoate, methyl benzoate and ethyl benzoate. Other products were benzyl alcohol, benzaldehyde, nitrobenzene, nigrosine, furamine (for dyeing furs), and a variety of sizings for textiles.

Newport Chemical Works, Inc., Carrollville, Wis.

This company is one of the few in the West engaged in the manufacture of coal-tar products. It utilizes the crudes supplied by the coke ovens of the Milwaukee Coke & Gas Co., and of the Northeastern Iron Co. It exhibited the various crudes, including phenol and pyridine, in a refined form, and the following intermediates: alpha naphthylamine, nitro naphthalene, di-nitro naphthalene, ortho-nitro toluol, para-nitro toluol, ortho-toluidine, para-toluidine, tolidine, 1 :3 :6 acid, H acid.

E. I. du Pont de Nemours Co., Wilmington, Del.

There was a diversified exhibit of fabrikoid and other products made by this company, apart from its main purpose of manufacturing munitions. The display of benzene, toluene, naphthalene, nitrobenzene, and dimethylaniline was limited to the raw materials which will serve in the extensive plans of the company to enter upon the production of dyestuffs.

The Calco Chemical Co., Bound Brook, N. J.

A very effective display of intermediates, including nitro benzol, aniline oil, aniline salt, dimethylaniline, dinitro-benzol, metaphenylenediamine, betanaphthol, sulphanilic acid, naphthionic acid, nitroxylol, xylidine and paranitraniline. The dyes regularly manufactured are: Acid colors—Scarlet 2 R, scarlet 2 R X, orange II, Bordeaux B, crimson Y, Bordeaux 2 B X, tartrazine. Chrome colors—Yellow, orange, green, brown. Basic colors—Methylene blue. Methyl violet. Direct colors—Orange R, maroon red, red, chrysamine, violet R. . Lake colors—Lake scarlet 2 R, lake scarlet 2 R X, acid orange, Bordeaux B, methylene blue, methyl violet. All of the dyestuffs were shown in solution. The sample dyeings were grouped together in a fan-shaped design, in front of which was an enormous cube of beta-naphthol. The whole arrangement was very effective.

The Williamsburg Chemical Co., Inc., Brooklyn.

The exhibit included the following intermediates: Benzylchloride, benzalchloride, benzaldehyde, benzoic acid, U. S. P., benzoate of soda, U. S. P., and dinitrochlorbenzol. But three dyestuffs are made by the company: Sulphur black, Malachite green, and Auramine. These were accompanied by sample dyeings. The whole display was very tastefully arranged.

New Jersey Products, Inc., Silver Lake, N. J.

Under this new designation appeared the products of the Thomas A. Edison Affiliated Companies. They were: Benzol, toluol, xylol, solvent naphtha, naphthalene, phenol, aniline oil, aniline salt, acetanilide, para-phenylenediamine, para-amidophenol base, para-amidophenol hydrochloride, para-nitro-acetanilide, benzidine, benzidine sulfate, acetyl-para-phenylenediamine. The coal-tar products made by the Edison companies are not many in number, but are manufactured upon a very large scale. Mr. Edison was one of the first, in 1915, to produce synthetic phenol and aniline in great quantities. He has limited subsequent expansion to a few important derivatives of these substances, notably para-phenylenediamine and para-amidophenol. Aniline is no longer produced for the market. The output of synthetic phenol continues, however, to be very large, and it is the intention to continue this feature indefinitely after the return to normal conditions, even in competition with phenol secured directly from coal tar. Both phenol and para-phenylene diamine are employed to quite an extent in the manufacture of records for phonographs and graphophones conducted by the Edison Co.

Butterworth-Judson Corporation, Newark, N. J.

A most imposing display was made by this company of the great variety of general chemicals manufactured in its extensive works. It is but recently that it has entered the field of coal-tar compounds. The list of intermediates now currently produced is, however, long and varied. The exhibit contained: Nitro-benzol, di-nitro-benzol, meta- and para-phenylene-diamine, benzidine sulphate, benzidine base, nitro-naphthalene, di-nitro-naphthalene, alpha-naphthylamine, naphthionic acid, ethyl-alpha-naphthylamine, methyl-alpha-naphthylamine, diphenylamine, H. acid, gamma acid, Neville and Winther acid, Schaeffer's acid, Cleve's acid, beta-naphthylamine, para-nitraniline, meta-nitraniline, para-nitrophenol, picramic acid, mono- and di-sulphonic acids, R acid, G salt, di-amino-tetra-methyl-benzophenone, di-amino-tetra-methyl-benzhydrol, benzal chloride, benzyl chloride, benzotrichloride, salicylic acid, salicylate of soda, methyl salicylate, phthalic anhydride, dimethylaniline. No colors were shown except Victoria blue and crystal violet. The company is now making phosgene and acetic anhydride on a large scale, especially for use in the manufacture of coal-tar dyes.

The Radcliffe Color and Chemical Works, Elizabeth, N. J.

Nigrosine is the chief product made at present. It was shown in all the standard forms, in blue, blue-black and jet-black shades, and oil, spirit and water soluble varieties.

The American Synthetic Color Co., Stamford, Conn.

The efforts of this company are now concentrated chiefly on intermediates. The products shown were picric acid, o-nitro-phenol, p-nitro-chloro-benzene, p-nitro-phenol and dinitro-chloro-benzene. The latter is the main element in the current output, and is supplied to manufacturers of sulfur black. The company is now producing large quantities of sodium nitrite, for the use of dyers and manufacturers of azo colors.

Empire Chemical Co., New Brunswick, N. J.

The activities of the company are devoted chiefly to intermediates. Its exhibit contained nitrobenzene, aniline, p-nitraniline, o-toluidine, p-toluidine, m-nitro-p-toluidine, p-nitro-o-toluidine, p-amido-phenol, and p-nitro-chloro-benzene. In addition there were various nigrosines.

King Chemical Co., Bound Brook, N. J.

The company displayed sulfur blue, sulfur black, methylene blue and primuline, accompanied by various direct reds, pinks, oranges and yellows. There was a good collection of sample dyeings.

Hellenic Chemical & Color Co., New York.

The dyes made by this company are methyl violet, methylene blue, bismarck brown, nigrosines, eosin, fuchsine, malachite green, and victoria blue. It specializes also in lakes and dry colors, and showed in this collection toluidine red toner, para red and para toner, phloxine lake and phloxine toner, magenta lake, rose lake and madder lake.

Dye Products & Chemical Co., Newark, N. J.

The company made a very creditable exhibit of intermediates and finished dyestuffs. The former included nitro-toluol, dinitro-toluol, meta-toluylene-diamine, diamine-developer C (crystals), toluidine, aniline and para-phenylene-diamine.

The chief colors represented were Naphthol green, Newark scarlet, Ponceau scarlet, Acid yellow, Chrome blue black, Chrome Brown, Copper purple, Chrysoidine, Eosin and Bismarck brown.

Madero Bros., New York.

This firm, while not manufacturing, is doing a large business as a distributor of chemicals, and especially of dyestuffs. It is rendering excellent service in building up foreign markets for our chemical products. It presented an excellent display of intermediates and of colors, including some made by the Monroe Drug Co., of Quincy, Ill.—notably H. acid.

Frank Hemingway, Inc., New York.

This company is, also, devoted largely to the distribution and export of chemicals and dyestuffs. It has, however, entered the field of coal-tar products, and manufactures on a large scale Michler's ketone, and various dyes made by its aid. The following colors were exhibited: Victoria blue B, victoria blue R, victoria blue 4R, crystal violet, malachite green, bismarck brown, primuline, safranine, paranitraniline, methylene blue. Attractive charts, with colored ribbons, outlined the genesis of each dye from coal-tar crudes.

Fifty intermediates were shown, among which were alpha-naphthol, alpha-naphthylamine, aniline, Bayer acid, benzidine, base and sulphate, benzaldehyde, benzyl chloride, beta-naphthol, beta-naphthylamine, Broenner's acid, dimethylaniline, dinitrobenzene, dinitronaphthalene, dinitrophenol, dinitrotoluene, diphenylamine, gamma acid (2:6:8), H acid (1:8:3:6), metaphenylenediamine, Michler's hydrol, Michler's ketone, naphthionic acid, Neville and Winther's acid, ortho-nitro-phenol, ortho-toluidine, para-amido-phenol, paradichlorobenzene, paranitro-phenol, paraphenylenediamine, para-toluidine, phenylaphanaphthylamine, phthalic anhydride, picramic acid, resorcin, R salt (2:3:6), salicylic acid, Schaeffer's acid, sulphanilic acid, tetranitromethylaniline, and xylidine.

A. Klipstein & Co., New York.

The exhibit of this long established firm, included numerous chemicals for the use of the dyer and tanner. Of especial interest were the sulfur dyes now made in quantity at Chrome, N. J., by the E. C. Klipstein & Sons Co. They embraced blacks, blues, yellows, browns and khaki tints. The zeta black is in demand for hosiery. Vat blues and indigo extract of this company are in extended use. An interesting feature was the collection of ciba colors and other coal-tar dyes, the products of the Basel Society of Chemical Industry, which the firm has imported regularly from Switzerland during the war, and which have done much to lessen the acuteness of the dyestuff shortage.

Geisenheimer & Co., New York.

This well-known importing and jobbing firm displayed a great variety of artificial colors, mostly from American works for which it is the selling agent. The most interesting feature of this extensive exhibit was the collection of dyes now made currently by the Ault & Wiborg Co., of Cincinnati, O. This company is one of the largest, if not the largest, producers of inks in the world. It requires normally very considerable amounts of a few staple shades. When cut off from European sources of supply in 1915, it promptly erected large works to furnish an adequate supply for its regular needs. The results were so successful that the output was notably enlarged both in quantity and variety. The colors exhibited were the following pigments: ambrose red, liberty toner and liberty red, all in various shades, and the following dyes: alizarin orange W, alizarin yellow G G W, chrome bordeaux, cloth red GO, acid bordeaux, acid orange No. 2, amaranth, azo crimson, brilliant acid orange G, croceine 3 B X, fast red A, induline N N, metanil yellow, ponceau G G, scarlet R R, tartrazine conc., eosin, erythrosin, Meldola blue and Bismarck brown R and Y.

The following intermediates, manufactured by Ault & Wiborg, were also shown: Amido-azo-toluol hydrochloride, amido-azo-benzol-hydrochloride, alpha-naphthylamine, alpha-naphthylamine-hydrochloride, alpha-nitro-naphthalene, aniline oil, aniline salt, Bayer salt 2:8, Broenner acid 2:6, beta-naphthylamine, beta-naphthol, dinitro-benzol, dinitro-chlora-benzol dinitro-toluol, monosulfonic acid F 2:7, nitro-benzol, nitro-ortho-chlor-benzol, naphthionic acid 1:4, Neville-Winther acid, ortho-toluidine, para-toluidine, paranitraniline, para-amido, acetanilide, para-nitro-chlor-benzol, phenyl-alpha-naphthylamine, R salt 2:3:6, Schaeffer salt 2:6, sodium naphthalene-beta-sulphonate, sulphanilic acid, tetra-methyl-diamino-diphenyl-methane and xylidine.

John Campbell & Co., Newark, N. J.

The company exhibited its "Amidine" series of direct cotton colors, the "Kromeko" series of fast chrome dyes, the "Aceko" series of acid colors and the "Liberty" series of dyes for the hat trade. The various intermediates employed in their manufacture were also shown.

Niagara Alkali Co., Niagara Falls.

This company is engaged extensively in the electrolysis of salt and markets the various soda products as well as chlorine, and bleach. It is now using large amounts of chlorine in the manufacture of chlorobenzene and exhibited this compound as well as dichlorobenzene. The latter was in the form of the commercial mixture of the isomers, as well as the pure ortho and para compounds. The whole exhibit illustrated admirably the degree of perfection attained in the development of the chlorine industry, as based upon electrolytic methods, and the use of the halogen in the production of coal-tar intermediates.

Hooker Electrochemical Co., Niagara Falls.

This company, also, had a fine display of the products of the soda and chlorine industry. It exhibited chlorobenzene, o-dichlorobenzene, p-dichlorobenzene, benzyl chloride, benzyl alcohol, benzaldehyde and benzoic acid. The manufacture of the last four compounds has been taken up quite recently.

This company was one of the first to show the advantage of transforming coal-tar crudes into their chlorine derivatives at the points where chlorine is produced electrolytically.

Merck & Co., New York.

In addition to a handsome display of alkaloidal, pharmaceutical and general chemicals manufactured by this company in their works at Rahway, N. J., there were exhibited a large number of their current coal-tar products. These included the pure hydrocarbons, benzene, toluene, xylene and naphthalene, aniline, p-nitraniline, acetanilide, benzidine sulfate, nitro-benzene, m-dinitro benzene, m-phenylene diamine, p-phenylene diamine, phenol, o-nitrophenol, p-nitrophenol, p-amidophenol, phenolphthalein, resorcin, hydroquinone, sulfocarbolates, b-naphthol benzoate, bismuth b-naphthol, salicylic acid, methyl salicylate, acetylsalicylic acid, acetphenetidin, salol, aurine, induline and nigrosine. The exhibit was instructive and revealed the wide range of activity of this long-established firm. Its coal-tar products are chiefly for medicinal and photographic use.

The Monsanto Chemical Works, St. Louis.

The exhibit of synthetic medicinals was finely arranged, and included the intermediates employed in making the different compounds. The coal-tar products shown were acetanilide, phenacetin, aspirin, phenol, U. S. P., phenolphthalein, saccharin, salicylic acid, salicylate of soda and salol.

This company is doing excellent work in establishing upon a solid basis the American manufacture of synthetic drugs from coal-tar crudes. It exhibited also vanillin, which it is now producing regularly.

Chromos Chemical Co., New York.

The exhibit was confined to fine samples of benzoic acid and sodium benzoate.

H. A. Metz Laboratories, Inc., Brooklyn.

The exhibit of this recently organized company contained an admirable display of its synthetic medicinals, salvarsan, novacain and anaesthesin. All of the intermediate steps in the production of salvarsan from aniline and arsenic acid were shown in carefully prepared samples. The establishment of the manufacture of this important synthetic drug on American soil is one of the leading features of the year's progress.

General Bakelite Co., New York.

Bakelite was shown in a great variety of forms, intended for the most diverse usages but chiefly in connection with electrical insulation. It is the trade name of a unique synthetic substance, oxy-benzyl-methylen-glycol-anhydride, discovered by Dr. L. H. Baekeland, after a series of brilliant research experiments, and is a condensation product of phenol and formaldehyde. In its pure form it is a hard, amber-like substance of pronounced chemical inertness. It combines high mechanical and dielectric strength with marked heat resistance and can be moulded with great accuracy and fine finish. It is also non-hygroscopic, impervious to water, steam, oils and most chemicals; has excellent weathering qualities, and will not warp, soften, swell or deteriorate with age.

This unusual combination of properties has rendered bakelite available for a great number of purposes. An especial degree of interest is attached to it as one of the few coal-tar products discovered in this country and introduced into general technical use.

The Stamford Extract Manufacturing Co., Stamford, Conn.

The successor to the old Stamford Manufacturing Co. displayed fine samples of the different dyewoods, as well as of quebracho, and the different extracts obtained from them in its large works. There were numerous examples of the results secured with them in dyeing. The hematin crystals were especially noteworthy.

The Obex Co., Marietta, O.

This firm is one of the latest to enter upon the production of dyewood extracts. It showed particularly fine cross-sections of Brazil wood, fustic, logwood and Osage orange, and a complete collection of the various extracts. The firm is planning to enter also upon the production of synthetic dyes.

Imperial Color Works, Glens Falls, N. Y.

Exhibits were made of lakes and toners made from p-nitraniline and from toluidine, in company with a variety of dry and pulp colors. There was also a good display of vegetable dyes manufactured in the plant of John H. Heald & Co., Lynchburg, Va. It included extracts of logwood, fustic and hypernic, hematine crystals, fustic crystals, wool and leather yellows.

The Buffalo Foundry & Machine Co., Buffalo, N. Y.

The exhibit of this company was the most imposing and the most extensive in the Exposition, occupying the entire western end of the main floor. It revealed in a remarkable way the complexity of the mechanism now employed in the production of chemicals and dyestuffs, and the contributions of mechanical engineering in this field. The company has been an important factor in furthering the rapid development of our domestic coal-tar chemical industry, by devising the requisite apparatus, and by rapidly supplying it in great quantities to newly organized firms.

The *pièce de resistance* at the Exposition was certainly its vast vacuum drum dryer, weighing 50 tons, with its two-stage dry pump, surface condenser and dust collector. One of the greatest successes in American foundry work is represented by the huge casing of the dryer, cast in a single piece.

A smaller vacuum drum dryer, in full operation, and an autoclave, holding 200 gallons, and working under 1,000 lbs. pressure, excited much interest, as did a jacketted receiver, an enormous nitrator, a capacious fusion kettle and a denitrator. There were numerous types of evaporators, for rapid circulation, for high concentration, for crystallization, with horizontal and vertical tubes, etc.

Among other forms of chemical apparatus shown by installation or plans, were: Acid eggs, acid concentrating apparatus, beta-naphthol plant, caustic flaking machines, caustic soda plant, causticizing apparatus, reflux condensers, crystallizers for TNT, ammonium nitrate, etc., vacuum crystallizers, expansion tanks, impregnating apparatus, nitric acid retorts and condensers, pumps, of many types; recovery systems for sulphuric and nitric acids, retorts (shelf type), salt filters, stills for aniline, beta-naphthol, phenol, etc., and sulphonators.

A large staff of engineers and chemists were in attendance, and the decorations and settings for the exhibit were in admirable taste. It testified in a striking manner to the exceptional claims which the chemical industry now makes upon the mechanical engineer.

J. P. Devine Co., Buffalo, N. Y.

A handsome exhibit of vacuum pumps, condensers, drying apparatus and high-pressure, cast-steel autoclaves, such as are now used extensively in making coal-tar intermediates and finished products.

The Pfaudler Co., Rochester, N. Y.

There was a fine display of the different forms of chemical apparatus, lined with resistant enamel, now required in variety by the manufacturers of coal-tar products, when dealing with strong acids. The specialties of this firm are highly appreciated in other countries, and a branch factory was maintained in Germany prior to the war.

Elyria Enameled Products Co., Elyria, Ohio.

The exhibit included a number of pieces of chemical apparatus, lined with enamel. This firm specializes in the production of enameled tubes.

Sowers Manufacturing Co., Buffalo.

An excellent display of steam-jacketted kettles, mixers, vacuum pans, etc.

Shriver & Co., Harrison, N. J.

Various types of filter presses.

United Filters Corporation, Brooklyn.

An instructive exhibit of new types of filters, in constant operation .

Kelly Filter Press Co., Salt Lake City.

Presses were shown in regular operation.

Arthur D. Little, Inc., Boston.

This firm is doing fine work as consulting and construction chemical engineers, and exhibited interesting evidences of the character of the work accomplished by its staff of 60, occupying a handsome building at Cambridge, Mass.

Civic, State and Railroad Exhibits.

A striking feature were the extensive collective exhibits of states, cities, railroad companies, and public organizations. Noteworthy in this connection were the large and instructive displays made by Louisiana and by Texas, as well as by the Southern R. R. system, the Carolina, Clinchfield and Ohio R. R., the Central of Georgia R. R., the Nashville, Chattanooga & St. Louis R. R., and the Norfolk and Western R. R. of Virginia. The South is making a vigorous effort to direct attention to the vast, undeveloped wealth in its territory, awaiting the advent of chemical industry. The great variety of samples and geological charts testified eloquently to the possibilities for creating manufacturing centers of mineral products in this section. The handsome exhibits of Baltimore and of Knoxville, Tenn., attracted much attention.

An official of one of the exhibiting railroads gave the following explanation of why his company found it desirable to participate in a chemical exposition:

"It might be wondered why a concern with but one product to sell, which, strictly speaking, is not competitive but is an essential—the absolute basis—of all industrial products, transportation should take the trouble, expend the money, and use up the time of part of its personnel to attend an exposition of this kind, but if you will look over the exhibit you will find that several railroads have done this. What is the reason?

"All railroads have at least two kinds of industries—those that 'just grow' and those that are planted. The first get there of their own accord, generally without the railroads' officials knowing or caring much about what was going on until their new neighbor began calling for cars; the second, the planted kind, often require nursing beyond the age when weaning is generally considered. These seem to me to be a middle ground, largely uninhabited, in matters of this kind which is much better for all concerned, and it is our firm belief, and I believe it is that of all of the increasing number of railroads who are taking advantage of this great opportunity to show their wares, that those roads which pursue a broadminded and liberal policy toward the intelligent aiding of new enterprises to become substantially established are they whose securities will be the real investment of the future."

ADDRESSES AND LECTURES.

In addition to all the many features appealing to the eye, not only in the diverse exhibits, but also in the daily production of many admirable series of motion pictures, portraying various phases of chemical industry, the management of the Exposition provided a very extensive list of lectures, addresses and symposia, dealing with a large number of chemical topics of timely interest.

In most of these the patriotic note was prominent and revealed the intense earnestness with which the American chemist faces his responsibilities during these days of strain and stress.

From the addresses the following extracts are made, as especially pertinent to the current situation or bearing upon topics connected with this section of the Chemical Engineer.

Mr. Roth Opens Exposition.

On the opening day Mr. Charles F. Roth, the manager of the exposition, in welcoming the assembled chemists, called attention to the fact that chemistry had swayed the balance of power among the nations, had revolutionized warfare, and made its ends more destructive and conquests more rapid. It had, in fact, transformed the entire industrial life of the United States and established the nation in the foremost rank of the industrial nations of the world. In closing he stated:

"A noted German chemist once said America was the natural home of the coal-tar industry. We are proving that now and building to make it permanently so. Not only of this industry is this true, but of all other chemical industries. Our raw materials have in the past been exported and returned to us in the manufactured form in which we used them.

"The exposition has done and is doing much to further the development of a complete cycle of domestic chemical industries. It will this year inspire us to a greater feeling of security for the future, showing that many fields are now efficiently producing and that we shall be in good position to not only fill all domestic needs, but to meet foreign competition in distant lands where a trade for the products of our chemical industries is already developed."

Dr. Charles H. Herty Praises American Chemists.

Dr. Charles H. Herty, chairman of the exposition advisory committee, followed with a stirring address, outlining the work now being accomplished by American chemists:

"The services of the chemist to the nation in these unusual times have been prompt, efficient and lasting Our soldiers soon to enter battle should be protected by the most lavish use possible of high explosives. Every possible pound of high explosive that this country can produce should be manufactured and transported to the European battlefields. Trench warfare has met its master in high explosives. The terrible sacrifice of life can be lessened by the curtain of artillery fire.

"There is no time to lose. High explosives must keep pace, nay, must increase faster than our man power. When writing out my address I did it by gaslight, and I hated the thought that I was burning gas which contains toluene, every trace of which should be on its way to Europe in the form of trinitrotoluol.

"Within the ranks of that army now being formed for battling in the cause of freedom are many of our young chemists—some from the industries, some the seniors and graduates from the universities. At Princeton all are gone, at the University of North Carolina every senior chemical engineer has enlisted. At the Massachusetts Institute of Technology the new course in chemical engineering has been abandoned until after the war, because all of the advanced men, who prepared to enter the course this fall, have enlisted, and so it goes all over the land.

"The battle for national self-containedness in that portion of the line held by the American chemist is progressing favorably. It is not yet won, but many heights have been conquered, many formidable streams crossed, and the open plains of full national service are almost in sight. The exposition, increasing in magnitude each year by 100 per cent. of its original size, constitutes the bulletin by which the nation is informed of the progress made.

"In the center," Dr. Herty continued, "the advance up the steep slopes of 'capitalization' has been marked. In 1915 there was added to the chemical industries $65,565,000, in 1916 $99,244,000, and in 1917, up to Sept. 1, $65,861,000, a total gain of $230,670,000. On the extreme right the forces of 'empiricism' have steadily yielded ground to the advances of our research chemists. More and more called upon for utmost effort, they have never failed to respond. On the left flank a steadily increasing force of the ablest American chemists is being gathered to capture the hill of 'obsoletism of army equipment' and is providing the great armies we are now raising with the most efficient forms of modern chemical means for both offensive and defensive warfare.

"On the right center the terrain of 'Congressional apathy' has been partly won, as typified by favorable protective legislation for our dyestuff industry and by the guarding of the all-important electrochemical industries at Niagara Falls from power shortage, due to lapsing legislation. On the left center the quagmire plains of 'public indifference' have been largely dried and made passable through the clearing skies of a sympathetic daily press, which has constantly emphasized the value to the independence of the nation of a full-rounded chemical industry. Finally, the counterattacks of subtle propaganda aganist the ability of American chemists and the worthiness of our products, such as American dyestuffs, have ingloriously failed. The optimism engendered by such splendid progress will prove, however, a curse, indeed, if it leads us to overlook the serious features of the present situation."

Prof. Stieglitz Tells of Progress.

Prof. Julius Stieglitz, of Chicago, president of the American Chemical Society, in his forcible address said:

"Every cloud has its silver lining, and even the great black cloud of war which has been oppressing the world these three years has been penetrated here and there by bright rays of good accomplished. One of these brighter effects of the disaster, so far as this country is concerned, has been the influence of the war on our chemical industries. Facing the necessity not only of very greatly expanding their output, but also of developing many new products and of making older products of a far higher grade in quality than ever before, our American industries, as evidenced by the three great expositions held in this place, have met and conquered one great problem after the other. We may confidently expect, and indeed we must insist, that out of this period of forced effort we shall emerge independent of all foreign nations in regard to our ability to supply the basic chemical needs of our country, not only in quantity but also in quality.

"As a single instance of the progress these years have witnessed in a field we must continue to hold after the war, let me recall the dismay of our universities—and, I am sure, also of our industrial laboratories—when early in 1915 we saw the supplies of Jena glass and of other finer glass cut off. Yet today we are manufacturing in the United States glassware as good as, if not, indeed, superior to, the German brands we thought we never could do without. When the war is over, no matter how fierce trade competitions may be, we must see to it that our new industries survive, that we do not relapse into our old dependence on European sources for almost every article in which quality, the higher quality, is essential.

"In the heat of effort of these years only the most urgent and immediate of our needs have been met. Some of these results still depend for their stability upon war conditions; they are still too liable to collapse when the world returns to its normal life and trade is free once more. In this situation, fraught with magnificent possibilities for much greater chemical achievements, but also with great dangers for the permanency of some of the American chemical industries, the American Chemical Society, for which I am speaking, sees its opportunity of being of new and still greater service to the country. Including in its membership of more than 10,000 the great majority of leading technical chemists as well as practically all the foremost men of the chemistry staffs of our universities and colleges, the society is in a position to render service in any branch of chemistry, service that will be expert and at the same time judicial and unbiased in its spirit.

"Thus, the society, influenced by the conviction that our national welfare demands independence in dye manufacturing, was active in aiding the movement to secure a much needed measure of protection by duties on dyes."

Dr. Colin G. Fink on Electrochemical Products.

Dr. Colin G. Fink, president of the American Electrochemical Society, said:

"Never before in the history of electrochemistry has the vast importance of the various electrochemical products been so forcibly brought to the attention of our Government and of our people as in the present year of the great war. Take from this country the electrochemical industry, with its numerous and diversified manufactures, and the martial strength of our country is hopelessly crippled. Think of the hundreds of machine shops that are utterly dependent on the electrochemical abrasives, carborundum and alundum! Think of the thousands of rifles and guns turned out every month with the aid of high-speed steel made from electric ferro alloys! Think of the millions of pounds of electrolytic copper that are absolutely essential for our electrical apparatus! There is the airplane, whose light, strong stays are made from the electrochemical metals aluminium and magnesium; there is liquid chlorine, a product of the electrolytic cell and basis of the Carrel-Dakin method of treating the wounds of our heroes; there is electrolytic hydrogen, used in all of our scout and observation balloons, and there are numberless electric alloys entering into the composition of nearly every item of the Government's vast military equipment."

More Chemists Needed, Says Prof. Bogert.

Prof. M. T. Bogert, of Columbia University, chairman of the chemistry committee of the National Research Council, outlined very fully and vividly the nature of the work now being done by American chemists to add to the country's effective power during the world conflict:

"Our committee was organized before the outbreak of the war by the National Research Council at the request of President Wilson through the agency of the National Academy of Science with the co-operation of the American Chemical Society. Its business consisted of: the co-ordination of scientific activities under various sub-committees; a census of research chemists. Returns from this census have been classified and indexed, and all sub-committees have been furnished with lists of chemists experienced in particular lines of work; detail of drafted chemists to positions of value. Already more than 300 individual problems of widest range have been given careful consideration, and reports made to various departments concerning these problems. Its chief function has been to serve as a central clearing house and coordinating agency for the chemical research work throughout the country. It serves also as a bureau of information by which accumulated information is given wide usefulness. It is estimated by the British authorities from their longer experience in such matters that only one suggestion in 300,000 proved to be of real usefulness. The committee has raised funds to meet the expenses of its own activities.

"As a result of the committee's experience to date, chemists are needed in the following lines: For teaching, the recruiting stations of the chemical laboratories being the educational institutions; for the control and direction of industrial operations of all kinds; munitions, gas, metals, leather, rubber, oils, paints, etc.; for the inspection and analysis of Government supplies; to identify poisonous gases, to detect poisons in water supply; for the development of new plants and processes throughout the country, these being called for by increased demand and cutting off of former sources of supply; for small scale manufacturing operations in educational and research institutions; for the security and defense of the country by protection against the enemies' contrivances; as advisers to the Government as to the best existing knowledge on various subjects and as to the best qualified men to initiate whatever research may be needed; in the Government laboratories to supplement the present forces. Many reagents and synthetic drugs, needed only in small quantities and therefore not of any particular interest to the commercial manufacturer, are now being made in universities and research institutions just as is being done in England, and thereby are furnished materials of utmost importance for the prosecution of the war and safety of the country."

"Drafted chemists should be exempted on account of industrial needs. They are rendering just as valuable and important service as those in the trenches and should be given insignia to indicate such exemption, as is done in France. At present there are more volunteers for research than problems to be solved. The committee is trying simply to supplement the work of the existing Government laboratories, but the number of problems is daily increasing.

"Military power is dependent upon scientific efficiency. This was no more strikingly illustrated than by the Germans, who replaced their exhausted supply of Chilean nitrate by atmospheric nitrate. It is difficult to talk on this subject with its many ramifications at a meeting like this, so I will talk on only one or two of its phases.

"One of these is hydrogen. It may not be believed, but it is true that the balloon and the submarine are problems in common. There is the necessity of analyzing the hydrogen used in inflating balloons for the discovery of foreign matter likely to be detrimental to the balloon's fabric. Then there is the development or creation of static electricity in the fabric of the balloon. That is another thing the chemist has to look out for.

"American chemists have devised two automatic hydrogen detectors and turned them over to the Government. The purpose of these detectors is to warn the submarine crew of the escape of chlorine gas from the storage batteries.

"The first gas attack was made by the Germans on April 15, 1915. Within four days after this first attack the Allies had equipped 3,000,000 men with temporary gas masks.

"At the present time there are 15,000 workers in England alone engaged in making masks for the military forces. They are turning out 20,000 masks a day, while contracts had been made for 25,000,000. One hundred and fifty chemists in this country are working on the gas-mask problem for the American soldiers."

Much Interest in Dr. Baekeland's Address.

Dr. L. H. Baekeland, in an address upon "The Future of the American Chemical Industry," brought out many important points:

"We have carried the mass production of synthetic explosives to a point never dreamed of. With truth, it can be said that if it were not for one of our largest chemical manufacturing companies, which promptly rushed to the rescue of the Allies at the beginning of the war and furnished them with explosives of which they were short, the war might have been ended a year ago in favor of Germany.

"Since then the chemists of France and England also have shown abundantly what they can do when conditions require it, and everything points out that after this war is over the supremacy of Germany in some of the chemical industries in which she heretofore was a leader will be a thing of the past.

"As far as the mineral chemical industries are concerned this country, even before the war, could stand excellent comparison with Germany or any other country. In fact, when it comes to the production of acids and heavy chemicals, the United States in several of these branches was decidedly ahead of Germany. There is no doubt, however, that we were behind in the manufacture of synthetic organic chemicals, which include the coal-tar dyes. But there was nothing strange or abnormal in this situation. The importation of these products in the United States before the war did not exceed $10,000,000 a year, this covering more than 1,000 different kinds of products, all of which require special processes of manufacture, and some having to be worked in very small units. As a business proposition, there was little to attract shrewd American business men.

"If Germany specialized in this branch of chemical industry, it was merely because she did not have the same opportunities for enlisting in other fields of enterprise. In this country we had new mines to exploit, new fields to cultivate, new railroads to construct, and many more industries of immediate importance claimed the full attention of our men of enterprise or scientific training. No wonder then that a little paltry industry of the kind was neglected.

"Nevertheless, as far back as the early seventies, a few enthusiasts started the manufacture of aniline dyes in the United States. They were making quite some headway, but in 1883 they had to perch through unfavorable tariff legislation. At that time German agents were already at work in this country and were leading our textile manufacturers by the nose and they helped them in their lobbying for the lowest tariff on dyestuffs, claiming that Germany would serve them, furnishing them with what they called their 'raw material.' This situation acted as a boomerang and paralyzed our textile industries at the beginning of the war.

"Since then, this country has realized that we must not estimate the value of the color industry in dollars and cents, but by the direct bearing it has as a key to all other industries. A few cents' worth of the right kind of dyes decides whether a hundred dollars worth of textiles can be sold or not in the open market. What is most extraordinary, almost a wonder, and bears witness to the flexibility and adaptability of American enterprise, is that in less than three years we should have made ourselves independent of Germany in the line where she had the start on us since half a century.

"The steady development of our industries of heavy chemicals, in the mineral or inorganic line, will very probably proceed as in the past. America's greatest development will consist in the further extension of industries in the organic field.

"In a country blessed beyond comparison with all the necessary natural resources for a large chemical industry, with a home consumption greater than that of any other country, we are very short of cheap water powers. Our great development of the electro-chemical industries in the United States was due to the fact that for the first time we placed at the disposal of our industries abundant electrical current, at lower rates than it has been obtainable in the past by means of steam. We became the leaders in those industries. Niagara Falls and its industries became a byword of electro-chemical supremacy throughout the world. Since then all other countries have gone us one better in the production of cheap water power. Unless we change our present condition, it looks as if our electro-chemical industries, our leading chemical industries, were going to be wrested from us to find a more inviting home in Canada and in Norway. Unfortunately, here again the condition is one of 'dog-in-the-manger' politics. A hydro-electric plant as a Government enterprise would not involve much of a new departure as compared with that splendid example of good engineering, the Panama Canal."

Mr. Kies on America's Chemical Exports.

W. S. Kies, vice-president of the National City Bank, told of the development of American export trade in chemicals. "The capital invested in chemical production from 1880 to 1915 has increased about eight times. The number of employees in the industry during that period increased but a trifle over three times and the wages and salaries paid increased about five times—from $6,000,000 to $31,000,000. In 1914 the chemical industries of this country exported in round numbers chemicals, drugs and dyes to the amount of $27,000,000. In the fiscal year 1917 these exports amounted to $185,000,000. In explosives, the value of our exports grew from $6,000,000 in 1914 to $820,000,000 in 1917. Under the heading 'other explosives' the value of our exports grew from $1,000,000 in 1914 to $420,000,000 in 1917, showing that in the industries closely allied with chemicals the growth has been quite as striking as in chemicals proper."

Dr. Hesse on the Tariff.

Dr. B. C. Hesse dwelt upon the relations of the tariff to the manufacture of coal-tar chemicals:

"There are not a few products of even the coal-tar chemical industry in which an import duty may in effect become a premium on inefficiency in operation and management, particularly in those cases where the costs of the basic materials employed are substantially the same at home and abroad in such cases, after the manufacturing technique has been acquired and a degree of efficiency in operation and utilization fairly comparable with the maximum has been achieved, the sole disability to the foundation of the industry will have been removed and domestic makers should then be in position to compete on those goods with foreign makers in our own markets without any artificial help through protective import duty and thus give these articles to such of our other domestic industries as use them at prices equal to those anywhere.

"In order that too much time be not taken in getting going, the conditional five-year limit to the life of the surtax of 5 cents per pound on certain dyes and of 2½ cents per pound on intermediates was obviously inserted in the present dye and allied chemicals tariff, which, in my opinion, is a very wholesome and a very equitable spur to our domestic manufacturers."

Mr. O'Reilly on "Chemistry and the Banker."

Mr. G. A. O'Reilly, of the Irving National Bank of New York, spoke upon "Chemistry and the Banker":

"The true relation of banking to chemistry is found in the theory of practical everyday business. This theory must be taken seriously and literally by both banker and chemist if they are to derive the greatest benefit from each other and from business. Regardless of tradition and of personal inclination, they must descend from their respective pinnacles, whether of financial exclusiveness or scientific preoccupation, and get together in the intensely practical and really very comfortable atmosphere which the thoroughly up-to-date business man of today has created and prepared for them. If in doing this it becomes necessary to disturb an occasional delightful fiction, or to smash an occasional professional idol, it is believed that both may be done to the entire benefit of all concerned.

"The theory that the true relation between chemistry and banking is found in business finds considerable justification even in conditions existing before the war. When viewed in the light of the big, wonderful new things which war has brought into the world, the conclusion becomes irresistible. The indifference with which in former years private interest viewed national problems and difficulties finds but slight resemblance in the magnificent response which business everywhere has made to the nation's call.

"And so while considering the business relationship between chemistry and banking we should concede sufficiently to the business advantages which will result to both from a proper getting together, we must not lose sight of the fact that the big thing in this relationship will be the national interest. For us there are just two worthwhile things in the world today—one, to win the war; the other, to protect American interests afterward. Naturally, winning the war comes first, but preparations to that end should be definitely based upon the understanding that wars are to be won principally that nations may live in greater peace and security and prosperity afterward."

Banker and Chemist Must Learn Common Language, Says Arthur D. Little.

Dr. Arthur D. Little, of Boston, the well-known chemical engineer, dwelt upon the same theme:

"The formation of indigo in the plant is a chemical reaction no less than when indigo is made by synthesis in the laboratory. Bankers were not particularly interested in the laboratory work until it became a commercial success, whereupon they began to take a decided interest in the credit of the indigo planter. Agriculture, which is so fundamental to the well being of any country, depends very largely upon chemistry, which makes possible fertilizers, furnishes data upon which methods of civilization may be based, and revises methods for the utilization of what would otherwise be an absolute waste. For example, the utilization of cottonseed has added more than a hundred million dollars annually to the value of the cotton crop, and cotton itself has become the raw material for very diverse chemical processes of the highest importance, such as explosives, celluloid, lacquers, and other well known items of commerce.

"The chemist is made to feel that he speaks a foreign language when talking to the banker, but events of the last three years are changing that. The flying corps risks its life daily solely for the advantage of a different viewpoint. The banker is in as great need of a new viewpoint, and can avail himself of it very much easier and without such risks. The waste that the chemists see on every hand really hurts, but it seldom moves the banker. The chemists through the prevention and utilization of these wastes could doubtless do more than any other profession in paying the debts of the war. This certainly should interest the banker. Of scarcely secondary interest is the chemistry of insurance, and the work which chemists can do in preventing the great annual fire losses. If Niagara Falls ran coal instead of water, how long do you suppose it would be maintained for the sake of a spectacle, and yet great obstacles have been placed in the way of the chemical engineer who would utilize Niagara's energy more fully than at present without seriously endangering the spectacle."

Dr. Little on Dyestuffs.

Dr. Little, on another occasion, discussed the dyestuff situation:

"Roughly speaking 75 per cent. of the dyestuffs needed are made in this country, and of this three-quarters, some are made in such excess that a considerable export trade is carried on with friendly countries, especially England.

"Of others needed there is a shortage, and this is serious in such basic colors as Magenta, Methylene blue, Auramine, Methyl Violet and a few more. The prices of many of them are way up, which has lured into the business a number of minor concerns in which the art is lacking to secure adequate yields. Some also are under incomplete chemical control, and they fail to purify their materials properly. This is incidental to pressing need and hasty establishment which the whip of time will correct. On the other hand, the very highest praise should be awarded to the conscientious manufacturers who have strained every nerve to meet the country's needs, often at the expense of profit.

"We have then three-quarters of the dyestuffs needed, some aplenty and others scarce. In regard to quality American-made dyes are the same as German dyes, only there are not so many of them. If some small makers are still short in their yields the loss is theirs. If they do not purify their materials enough the defect is more likely to be in shade than in fastness. This is a complete catalogue of the defects of American-made dyes and it does not apply to the products of the important makers. Nevertheless, dyers have been sorely put to it. They have had to use one material when they wanted another, and the substitutions have often been unhappy. They have also been compelled to relearn the art of using dyewoods for many purposes which are new to the present generation, and this is not to be learned in a day. The trouble, however, has principally come from the makeshift substitution of wrong materials for the right ones, because the right ones are lacking. The colors themselves are the standard articles whether made in Germany, France, Switzerland, England or here. And missing and scarce products are coming upon the market as agreeable surprises at short intervals."

Mr. McKerrow on Dye Situation.

H. Gardner McKerrow dwelt also upon the same topic:

"In point of quality American colors will, for the most part, compare well with the best imported colors. Both as regards brilliancy, fastness to washing and light, and general wearing qualities, the new styles are fully equal to the well known German type, as indeed there is no reason why they should not be, for the making of a dyestuff is, given the requisite intermediates of good quality, simply the following out of a fixed formula and the carrying out of certain prescribed successive steps.

"The industry is well established and there is no longer any fear of a shortage of dyestuffs, or a shutting down of factories on account of an absence of colors, and the new fashions are showing as much variety and brilliancy of shade as ever. It is true that some of the more delicate and fancy shades are not yet obtainable in American-made dyes, and it may be some time before these are forthcoming, for the simple economic reason that they are used in comparatively small quantities and only by certain specialized industries, such as certain kinds of silk manufacture. Doubtless these specialized manufacturers feel themselves aggrieved because their needs are not among those which have been filled, and are inclined to say

ARTIFICIAL COLORS

The Discovery of Primuline

By Arthur G. Green

[Professor Arthur G. Green, who occupies the chair of Tinctorial Chemistry in the University of Leeds, contributes to the Journal of the Society of Dyers and Colourists the following interesting account of the circumstances attending the discovery of the valuable dyestuff Primuline. The article can be read with profit by all engaged in the manufacture of coal-tar colors, and especially by those entering upon the field of research. Prof. Green, in addition to his work as an investigator and teacher, is the author of the English edition of Schultz and Julius' "Tables of Organic Coloring Matters," and of "The Analysis of Dyestuffs" (1915).—Ed.]

In reading the published accounts of the early history of the coal-tar color industry I have often noted with regret the great paucity of information regarding some of the most important discoveries. Many interesting and valuable facts which could have been supplied by the pioneers of the industry have, through want of a historian, never been chronicled, and, now that most of these early workers are unfortunately no longer among us, must of necessity be lost. I have therefore thought that it might be of interest to the Society of Dyers and Colorists if I recorded, while there is yet time, a few personal reminiscences of a discovery which, though of less importance than some others which preceded it, has, nevertheless, come to be regarded as a landmark in the evolution of the dyestuff industry and of the art of dyeing.

The discovery of primuline took place in 1887 under circumstances which form an interesting illustration of the important part played by chance in very many discoveries. In the autumn of 1886 I was engaged in the laboratory of the late firm of Brooke, Simpson and Spiller, of Hackney Wick, London, in making a study of the sulfonation of amido-azobenzene with the object of producing an azo crimson for wool. I had entered the service of this firm at the age of twenty-one, direct from college in the previous year, and had, therefore, had but little experience of chemical manufacturing, although during the latter part of my University course I had enjoyed the advantage of being able to spend a portion of my summer vacations in the works of Messrs. Williams Bros. and Ekin, of Hounslow. While I was engaged upon the above-mentioned experiments, my attention was attracted to a patent taken out by the firm of Dahl and Co., of Barmen, which described the production of a new base said to be isomeric with diamido-ditolyl sulfide. As this base was stated to give a maroon when diazotised and coupled with b-naphthol-disulfonic acid, I thought its sulfonic acid might be used as a substitute for amido-azobenzene-sulfonic acid, the preparation of which had given me some trouble. Upon preparing this so-called "thiotoluidine" by the method of the patent I obtained only half the expected yield, while the other half of the p-toluidine remained unaltered. Furthermore, by titration with nitrite the base produced was found to contain only one amido group instead of two. Closer investigation showed that the reaction actually required four atomic proportions of sulfur to two molecular proportions of p-toluidine, and that the product (now known as dehydro-thiotoluidine) had the empirical formula $C_{11}H_{12}N_2S$. Upon treatment with fuming sulfuric acid it gave a sparingly soluble monosulfonic acid, the ammonium salt of which was also sparingly soluble. In studying the azo derivative obtained from this base and from its sulfonic acid the interesting discovery was next made that many of these dyestuffs had a substantive affinity for cotton. At this period the benzidine colors, discovered three years previously, were claiming much attention, and it was generally held that only azo compounds derived from paradiamines would dye cotton without a mordant. Here, however, was a class of direct dyeing cotton dyestuffs derived from a *mono* amine.

While the investigation of these new colors was proceeding, a paper appeared in the Berchte of the German Chemical Society by Möhlau (Ber., 19, 2,014), which attributed the direct affinity for cotton of the benzidine dyestuffs to the presence of the diphenyl residue, and in support of this contention asserted that cotton boiled in a solution of the hydrochloride of benzidine itself, took up and fixed the base, which could subsequently be converted into Congo Red on the fiber by passage through an acidified solution of sodium nitrite followed by sodium naphthionate. Knowing that my new sulfonic acid, like benzidine, gave substantive cotton dyestuffs, I was interested to see whether it also would exhibit a direct affinity. For trying the experiment I used the sodium salt of the unpurified sulfonic acid obtained by sulfonation of the crude thio base formed by heating 2 molecular proportions of p-toluidine with 4 atomic proportions of sulfur, and found that a hot solution of this product immediately dyed cotton a bright primrose yellow, while upon passing the cotton thus dyed through a solution of nitrous acid and thence, after washing, into solutions of naphthols, phenols or amines, a whole series of colors were obtained which exhibited great fastness to soaping. Thus in half an hour I was able to obtain on the fiber a yellow, orange, red, crimson, maroon and purple.

I was now much interested to prepare the new sulfonic acid in a chemically pure state, especially as I was somewhat astonished that it should dye cotton yellow, as I believed its salts to be colorless. As a means of purification, I accordingly prepared the sparingly soluble crystalline ammonium salt. This was, in fact, without color, but to my surprise exhibited no affinity for cotton whatever. On the other hand, the filtrate from which the ammonium salt had separated dyed as before. It was, therefore, clear that it was not the sulfonic acid of the so-called "thiotoluidine" which exhibited this property, but the sulfonic acid of another compound accompanying the "thiotoluidine" in the crude base, the ammonium salt of which differed from that of the former by being easily soluble. It occurred to me that this might be a more complex thio compound, and I accordingly made melts with a still larger proportion of sulfur, obtaining in fact an increased yield of the direct-dyeing sulfonic acid at the expense of the sulfonic acid of the simpler base. Further experiments showed the best condition for its preparation, and in the summer of 1887 the sodium salt of the sulfonic acid was put upon the market under the name of "Primuline," this name being derived from the word "Primula," the generic term for plants to which the primrose and cowslip belong.

And now I must mention a curious fact. It was not until a year or two later that I was led to repeat Möhlau's experiment upon the direct affinity of benzidine. Much to my surprise, I found that the supposed observation of Möhlau, which led me to try the experiment which disclosed the direct affinity of the sulfonate of the higher thionated p-toluidine, was an entirely erroneous one. Not a trace of affinity exists between cotton and benzidine, a fact which was also corroborated later by Levy. It is curious to reflect that had I first stopped to test the validity of Möhlau's statement, or had I used for my experiment the sulfonic acid of pure dehydro-thiotoluidine, I might never have discovered Primuline.

The chemical structure of Primuline and the related dyestuffs remained in doubt for some time after their discovery, and was only ascertained with certainty after a considerable amount of scientific work extending over the two following years, and in which several German investigators also took part. The dyeing properties of Primuline were first announced in the "Dyer" for July, 1887, and a full account of the dyestuff and of the "ingrain" process was communicated to this Society at Bradford on February 9, 1888, and published in the "Journal" for that year (page 39).

My firm unfortunately were not enthusiastic about the value of the new discovery. The managing director, upon being shown the diazotisation and development of Primuline, remarked sarcastically, "Yes a very pretty experiment; you had better show it to the Chemical Society!" inferring that it had no commercial value. If it had not been for the encouragement given me by the late Mr. Edward Brooke the dyestuff might never have been introduced into commerce. As it was, nothing would persuade them to patent it. To my urgent requests in this direction they replied, that either the discovery was valueless, in which case a patent would only be a waste of money, or if it was of value a patent would disclose its composition, and enable competitors to manufacture it, for after their previous experience with the Magenta patent they would never engage again in a patent action and, therefore, could not defend the patent if infringed. I prepared draft specifications for three separate patent applications, covering (1) the manufacture of Primuline, (2) the production of dyestuffs upon the fiber by the diazotising and developing process, (3) the production of a variety of azo dyestuffs in substance derived from Primuline and dehydro-thiotoluidine sulfonic acid. My board of directors, however, declined in their superior wisdom to apply for any of these suggested patents, which would have covered an enormous field and have been of immense value to the company. By this action and others of a similar character they condemned their firm to continued decadence and to ultimate extinction, while at the same time the whole dyestuff industry of England was adversely affected. Who can doubt that had a more enterprising policy been followed the stimulus of successful progress would have reacted advantageously on other English firms, and have given encouragement to other English chemists to devote their abilities and energies to dyestuff research? Even when the commercial success of Primuline was assured, my firm declined to make any adequate recognition for the discovery, and only after considerable pressure did they consent to pay a small commission. The last payment of this commission, covering the six months preceding my leaving the service of the company in 1893, amounted to the large sum of 83 cents, although the sale of the dyestuff remained undiminished and the average price was then about 60 cents per pound. I only mention these facts to show the small encouragement which was given to young chemists at that period.

The result of the policy of secret manufacture which they preferred to follow was exactly what might have been foreseen. Upon the appearance of Primuline in commerce the German firms at once recognized its importance, and submitted it to chemical examination. Its composition was quickly solved, and within a year or two its manufacture was commenced by two of those firms (the Farbenfakriken F. Bayer and Co. and Messrs. Dahl and Co.), while a third (Messrs. Meister Lucius and Brüning), supposing the dyestuff to be patented, applied to my firm for a license, and had to be informed that they were free to manufacture it if they knew how. The Badische Anilin Co., who also unravelled its composition, were dissuaded by Dr. Caro, on moral grounds, from undertaking its manufacture, but commenced a few years later. Dr. Ehrhardt, the late head of the patent department of this firm, stated in a recent publication that from computations which he had made, based on the sales of Primuline by his own and other German firms, he had no hesitation in saying that "with adequate protection the invention of Primuline alone might have brought in a princely income, and, properly managed, should have contributed largely towards placing the (English) factory in the front rank of chemical manufacturers of the world."

Manufacture of Copper Compounds of Ortho-Oxy-Azo Dyestuffs

We have had occasion to describe various new dyestuffs obtained by Dr. Carl Jagerspacher of Basel and his associates, on treating ortho-oxy-azo dyestuffs with copper compounds in the presence of a solvent.

In a later patent (Amer. Pat. 1,237,183 of Aug. 14, 1917) Dr. Jagerspacher and Dr. G. Engi find that instead of starting from the ortho-oxy-azo dyestuffs and acting with copper compounds on their solutions, the new copper compounds can also be obtained by effecting the combinations of ortho-oxy-diazo-phenol or ortho-oxy-diazo-naphthol derivatives with azo dyestuff components, in presence of copper compounds. Thus the copper compounds of the ortho-oxy-azo dyestuffs are produced directly and can be isolated eventually after addition of common salt, by filtration, washing and drying.

In this connection they make the observation that generally the combinations in presence of copper compounds occur more easily than according to the hitherto usual methods. The reaction is facilitated in such a manner, that certain combinations, which could not be carried out, or could only be carried out with low outputs, according to the usual methods, can be executed now easily and with excellent yields by effecting the reaction in presence of copper compounds. While for instance the combination of the diazo derivative of 1:2:4-amino-naphthol-sulfonic acid with 1:5-naphthol-sulfonic acid was, according to the known methods, very incomplete and the yield extremely low, the yields of copper compounds of the said ortho-oxy-azo dyestuff obtained according to the new process in presence of copper salts are almost quantitative.

The new process is illustrated as follows:

Example: To a concentrated solution of 25 parts 1:5-naphthol-sulfonic acid and of 40 parts sodium carbonate in water is added, while stirring, a solution of 24 parts copper sulfate in 60 parts water. In the solution thus obtained is introduced, while stirring, the diazo derivative of 24 parts of 1.2:4-amino-naphthol-sulfonic acid, prepared in the usual manner. After stirring for 24 hours at ordinary temperature, the reaction mass is heated progressively to 40° C. and maintained at this temperature until the combination is achieved. After separation of the copper hydroxide in excess by filtration, the copper compound is precipitated from the solution by adding common salt. It dissolves in water with violet-red and in concentrated sulfuric acid with blue coloration and dyes wool in an acid bath pure violet tints fast to light, washing and alkalis.

New Azo Dyes from Chromotropic Acid

James H. Stebbins of No. 80 Madison Avenue, New York City, has recently patented (Amer. Pat. 1,235,253, of July 31, 1917) a new class of dyes, derived from chromotropic acid, or 1.8-dioxy-naphthalene-3.6-disulfonic acid,

$$C_{10}\,H_4\,(OH)\,(SO_3H)\,(SO_3H)\,OH\ [1:3:6:OH]$$

The new dyestuffs are derived from the acid, by combining it with diazotized benzidine, or its equivalent, and with another diazotized aromatic amine, such as diazotized p-nitraniline or diazotized p-amido-phenyl-glycine or diazo-picramic acid; and by further combining with the diazotized benzidine an end component such as 1.5-naphthol-sulfonic acid or the 1.4-naphthol-sulfonic acid.

The dyestuffs are characterized by the following constitution:

$$R—N:N—R_1—N:N—R_2—N:N—R_3$$

in which R_1 is the nucleus of the chromotropic acid, R_2 the diaryl nucleus of benzidine or its equivalent, R_3 an aromatic nucleus of an end component such as a naphthol-sulfonic acid, and R an aromatic nucleus derived from a diazotized aromatic amine such as those referred to above. These dyestuffs form blue, black or brown products, soluble in water and capable of dyeing cotton in sodium sulfate baths bluish or purplish shades, and also capable of dyeing wool in acid sodium sulfate baths blue to black or brown shades. Mordants are not required in either case.

The following example illustrates the general method:

Example 1: 13.8 kgs. of p-nitraniline are diazotized in the usual way by treatment with 60 liters of hydrochloric acid of 1.2 specific gravity, diluted with 200 liters of water, and 6.9 kgs. sodium nitrite dissolved in 200 liters of water. The diazo-p-nitraniline chloride solution thus obtained is then gradually stirred into a solution of 40.4 kgs. of the sodium salt of chromotropic acid in 100 liters of water. At the end of the operation, it will be found that the solution has a strong acid reaction. A bright scarlet dyestuff is thus obtained. The dye solution is allowed to stand over night. It is then made alkaline by the addition of 140.0 kgs. anhydrous sodium carbonate which is sufficient to neutralize the 60 liters of hydrochloric acid previously used and 37.5 liters of hydrochloric acid to be used in the next operation. A dark blue precipitate with a purplish solution is formed. On heating to boiling the precipitate is dissolved yielding an intensely purple solution. On cooling the dyestuff separates in the form of its sodium salt, as a semi-solid mass of crystals. The crystalline mass is then broken up by stirring and treated under constant stirring with one molecular proportion of tetrazo-diphenyl chloride. The solution immediately turns back with the formation of a black precipitate of the new intermediate product. The mixture is allowed to stand in the cold for about 6 hours. There is then stirred into the same a solution of 22.4 kgs. of 1.5-naphthol-sulfonic acid dissolved in 300 liters of water and the whole is made alkaline with 16 kgs. of caustic soda. The black precipitate of the intermediate begins to dissolve immediately, yielding a violet-colored solution. On standing, it is ultimately transformed into a violet-black precipitate with only a small amount of coloring matter in solution. The precipitate is filtered off and dried.

The new azo dyestuff thus produced dissolves in hot water with a bluish Bordeaux color. On cooling it partly separates out again. It dyes unmordanted cotton in a neutral sodium sulfate bath a bluish shade. Silk and wool are dyed in an acid bath of sodium sulfate various shades of brown to black, depending upon the quantity of dye used.

The tetrazo-diphenyl chloride referred to in the above example may be prepared from benzidine as follows:

18.4 kgs. benzidine are dissolved in 37.3 liters of hydrochloric acid of 1.2 specific gravity and 300 liters of water. The solution is cooled with ice and diazotized by treatment with 13.8 kgs. sodium nitrite dissolved in 300 liters of water.

New Class of Dyes from Patent Blue

Dr. Fritz Funcke and Dr. Carl Jagerspacher, of Basel, Switzerland, assignors to the Society of Chemical Industry (Amer. Pat. 1,237,192 of Aug. 14, 1917), describe a series of leucotriaryl-methane dyestuffs obtained by diazotizing the amido-leucopatentblue, resulting from the nitration of leucopatentblue and subsequent reduction, and by combining the diazo body with an azo dyestuff component, as for instance an amine, a phenol, a naphthol, an aminophenol, an aminonaphthol or their sulfo or carboxyl derivatives, pyrazolone derivatives, etc.

The new dyestuffs dye on mordant and are especially applicable for dyeing animal fibers vivid blue to green tints, fast to washing and light. They constitute blue to green and yellow powders, soluble in water, with blue to green and yellow colorations and in concentrated sulfuric acid with yellow to violet colorations.

The new process may be illustrated by the following example:

Example: 57 parts of amido-leuco-patentblue prepared by nitrating leuco-patentblue (dyestuff obtained by condensing m-nitro-benzaldehyde with diethyl-aniline, reducing the resulting nitro body, diazotizing, boiling the resulting diazo derivative and transforming the thus obtained oxy body into disulfonic acid, with a mixture of nitric acid and sulfuric acid and reducing the resulting nitro derivative, are dissolved in about 250 parts of water at 40° C. and 25 parts soda lye of 30%. To the solution thus obtained are added 7 parts sodium nitrite and the mass is acidulated at 0° C. by adding 40 parts concentrated hydrochloric acid. The resultant solution of the diazo derivative is poured into a solution, as concentrated as possible, of 14 parts b-naphthol, 13 parts soda lye of 30% and 50 gr. sodium carbonate. After the mass has been stirred or allowed to stand for several days, the combination, which proceeds very slowly, is completed and the dyestuff is salted out. It constitutes a blue powder dissolving in water with a blue and in concentrated sulfuric acid with a brown-violet coloration. It dyes wool in an acid bath green-blue tints, which by their treatment with chromium compounds become fast to washing and to light. They turn to a blue fast to washing and to light by treatment with copper compounds.

In an additional patent (Amer. Pat. 1,237,193 of Aug. 14, 1917) the inventors describe, as follows, the preparation of copper derivatives of the dyes in question:

Thirty-five parts of the dyestuff, obtained by combining the diazo derivative of amido-leuco-patentblue with b-naphthol, are dissolved in 1,000 parts tepid water. To the solution is added at 70° C. a solution of 13 parts of crystallized copper sulfate in 50 parts water, whereby the green-blue coloration of the solution turns to blue. The resulting copper compound is precipitated by addition of common salt, isolated by filtration, pressed and dried. It constitutes a blue-black powder, soluble in water with blue and in concentrated sulfuric acid with green coloration. The new copper compound dyes animal fibers in an acid bath pure blue tints very fast to light and to washing. Especial importance is attached to the copper compound of the dye-stuff derived from the diazo derivative of leuco-amido-patentblue and 1-phenyl-3-methyl-5-pyrazolone. This constitutes a black-green powder soluble in water to a pure green solution and in concentrated sulfuric acid to orange red solutions. It dyes animal fibers in an acid bath pure green tints, fast to washing and to light.

NATURAL DYES

Development of the Natural Indigo Industry in India

By Professor H. E. Armstrong

[The growing interest in the possibilities of re-establishing the widespread use of natural indigo was briefly mentioned in the June issue of this journal, page 137. The following study by Professor Armstrong, a leading British chemist, will be read with interest in this connection. As stated in our June issue, the problem is one of importance for our South Atlantic States, in which the culture was pursued so successfully during the 18th century.—Ed.]

So-called "synthetic indigo" has been manufactured in large quantities of late years, mostly in Germany and to a much smaller extent in Switzerland, the raw material being derived from coal tar. It is usually supplied in the form of a paste containing 20 per cent. of the dyestuff, free from impurities apart from water. The term "synthetic," be it noted, is applied to all substances "put together" in the laboratory. Synthetic indigo consists of a single definite compound known as *Indigotin.* Natural indigo contains this same indigotin, together with certain impurities, of which there is rarely less than 30 per cent. In addition, it regularly contains small but varying amounts of indigo red. The presence of this latter constitutes the main difference between the artificial and natural indigo as a dyestuff. Synthetic indigo has now a strong position, particularly among calico printers, because it may be completely discharged, leaving clear whites on patterned goods. It has no advantage, as a dyestuff, in dying heavy uniform shades. Indeed, most dyers give the preference to natural indigo for this purpose, owing to the effect the indigo red has on the shade, though few, if any, are prepared to pay a higher price for it on this account. Natural indigo was ousted from the market mainly because of its irregular composition; also because of the difficulty and cost of grinding it to powder.

The amount of "synthetic" paste produced in 1913 is believed to have been about 55,000 long tons, of a value of $16,070,000. The export to Great Britain in 1913 was 1,180 tons; to India, 324 tons; and to China and Japan about 27,000 tons.

The export of natural indigo from India, reduced to a basis of 20 per cent. paste, was slightly over 2,000 tons in each of the years 1910-11 and 1911-12. It fell to less than 1,500 tons in the two following years. It then rose to 2,142 tons in 1914-15, and to 5,242 tons in 1915-16.

Outlook for Industrial Revival.

When in Calcutta in November, 1914, I found that the revival of the industry was already under discussion, owing to the fillip which the war had given to the sale of indigo. I then took the opportunity of gathering what information I could. My opinion of the prospects was expressed in a letter, which I wrote before leaving to the *Statesman,* of Calcutta, in the following terms:

"If the advantage gained by natural indigo through the war is to be maintained, I believe it will be necessary for planters, in future, in some way to arrange to bulk their products and put upon the market a paste of fixed composition, comparable with that supplied by the Germans.

"I cannot help thinking that it should still be possible to secure a fair share of the trade for natural indigo in competition with the synthetic article. The possibilities in the way of effecting improvements, especially in agricultural practice, in the plant itself and in the process of manufacture, seem to be in no wise exhausted. Our understanding of such matters is now so much greater than it was even 10 years ago. Various inquiries have studied this or that side of the problem, but apparently no attempt has been made to deal with the subject comprehensively from the many points of view, from which it must be regarded, if success is to be assured. The men who have been engaged have not had the all-round knowledge or the ripened ability as investigators that is required to deal with the many issues, scientific and economic, that are involved. It cannot be insisted too strongly, in fact, that the problem is one requiring very special knowledge and acumen. But it is nothing short of a disgrace to us that such an industry should be allowed to lapse in a country where the need of native industries is so great. The recovery of the position of natural indigo may be a costly business; but if one-tenth of the zeal, put by the Germans into the production of the artificial pigment, is brought to bear on the problem, I believe it will be solved satisfactorily."

An official conference was held at Delhi early in 1915, and as a result the matter came under discussion at the India Office. Eventually an agreement was entered into with the Bihar planters, and it was resolved that the necessary steps should be taken to study and develop the industry with competent scientific aid.

Considerable progress was made last year. Important improvements are already foreshadowed in agricultural practice, which should increase the crop and render it more certain. It is also clear that the methods of extracting the dyestuffs may be developed so as to increase the yield and improve quality. Not least important, the advantages to be derived from co-operation are being brought home to planters. Recently the Madras Government has consented to the imposition of a small duty on exports of indigo. The proceeds are to be utilized in carrying on experimental inquiry. Steps are now being taken here to reduce Bengal indigo to a paste of uniform composition before offering it to dyers.

It has already been demonstrated, on a practical scale, that natural indigo may be produced and sent here in paste form, comparable with that in which synthetic indigo is put upon the market by German and Swiss manufacturers.

I am strongly of the opinion that dyers, therefore, should not commit themselves, in advance, too hastily to the synthetic product, and regard this as the more suitable material. They may expect that natural indigo will be supplied in all the various forms in which it is now required, ready for use, eventually at prices which will put it on a level with the artificial material, manufactured by German methods, even if made here. It is essential, however, that users should, for a time, give their patriotic support to the effort.

Algarrobin

The bark of the carob tree, occurring in great abundance in Argentina, contains notable amounts of a natural dyestuff, the extraction of which has recently assumed industrial importance.

Algarrobin, as the extract is termed, contains a high percentage of tannic acid, and is found to give excellent results in tanning. The tinctorial properties are, however, so marked that it is felt as if a very distinct field may be open for its use in dyeing. It is susceptible of application to both animal and vegetable fibers, imparting a clear chestnut brown, which is very fast to both light and washing.

The most advantageous use of algarrobin appears to be in conjunction with other vegetable dyes. It modifies tints and simultaneously, on account of the high tannin content, acts as a mordant. There appears to be, also, an abundant opportunity for its use as a bottom for numerous coal-tar dyes.

In the weighting of silk algarrobin may come into close competition with gambier, as the fiber absorbs materially larger amounts of the former. When used alone the color imparted to the silk is brown as compared with the yellow of gambier. The addition of tin phosphate to the bath gives a much darker lake than in the case of gambier, and the iron lake is practically black. In all cases silk weighted with algarrobin is equal in feel and luster to that treated with gambier, and frequently superior.

France and Italy are now employing large amounts of algarrobin for dyeing khaki and olive drab on military uniforms. It may be of marked assistance in meeting the heavy demand for coloring materials, associated with the manufacture, on so extensive a scale, of the fabrics required to clothe the American army in the immediate future.

The dye is produced regularly in a factory at Santa Fé, in the Argentine Republic, with a daily capacity of over six tons. McKitterick and Simpson, 200 Fifth Avenue, are the New York agents.

The British Imperial Institute published recently the following details on the methods of dyeing with algarrobin, secured through correspondents in Argentina:

Cotton—The cotton is placed directly in the algarrobin bath, the dye to be dissolved in pure water, adding at the most 200 grammes of acetic acid to 100 kilos of the extract. It is not necessary that the solution boil during the dyeing, but sufficient if the bath is kept at a good heat during from ½ to 2 hours for the dark colors and from ½ to 1 hour for the lighter shades. The spools must be stirred from time to time, and it is preferable to keep them submerged.

The cotton dyed in this manner is left to drain and cool in the open air, and is then placed in the mordant bath (mordant of iron cold and other mordants lukewarm); it is recommended to see that the color is well fixed before taking the cotton out, afterwards washing with care.

To Dye Cotton Black—First bath: Dissolve the algarrobin in boiling water at the rate of 25 per cent. of the weight of cotton to be dyed, for the first bath only; for the following lots it will be sufficient to add about 10 per cent. every time for the bath to retain its strength (it is advisable to add 1 per cent. of logwood or ematina). The cotton is placed directly in the dye, stirring well, so that every part gets well soaked, then submerging entirely during from two to three hours, after which the cotton is brought to the surface again, stirring repeatedly. The yarn so dyed is taken from the bath, and when the dyer has brought the bath to its original strength the second lot of cotton is put in it.

Second Bath: After the first lot of cotton has remained in the open long enough to be thoroughly oxidized, it is placed in a 5 per cent solution of sulfate of copper of a temperature from 40° to 50° C., stirring continually until the mordanting process is quite completed (about 1 hour), then washing, using fresh water twice and stirring well. The shade then obtained must be very dark brown.

Third Bath: Dissolve in boiling water 1 per cent. ematina (the alkaloid obtained from ipecacuanha), or 2 per cent. logwood extract, and soap 0.2 per cent The yarn is placed in this bath, stirring immediately, so that the fluid covers the spools evenly. After ½ to ¾ of an hour a perfect black is obtained; wash and dry immediately.

When dyeing with two men and two tanks, one for the algarrobin solution and the other for the second and third baths, three lots of cotton have to be worked at the same time:—One lot, 50 kilos, in the algarrobin solution; one lot, 50 kilos, exposed to the open air; one lot, 50 kilos, passing through second and third baths.

It is recommended that mordanting be done with the greatest care, and the solution must be spread rapidly over the entire spool in order to obtain a uniform shade. The same applies to the ematina or logwood bath. If in the mordant bath the color becomes greenish, 1 per cent. of iron, thoroughly dissolved, must be added.

The cost of dyeing black with algarrobin works out at:—

Algarrobin	15% at $1.50 =	$22.50
Sulfate of Copper.......	4% at .75 =	3.00
Ematina	1% at 10.00 =	10.00
Labor and general expenses, 20%........		7.10
Total cost for 100 kilogs. cotton..........		42.60

Dyeing of Wool and Silk—As in the case of all animal fiber, it is recommended to apply the mordant before dyeing. For the Havana brown shades the best results are obtained with bichromate of potassium (or sodium) as a mordant.

To Dye Black—First Bath: Bichromate of potassium, 1 per cent.; sulfate of copper, 3½ per cent.; sulfuric acid, 1½ per cent. Soak from 1 to 1½ hours at 80°-90° C.; take from bath and wash.

Second Bath: Algarrobin, 15 per cent. Soak from 1 to 1½ hours at 80°-90° C.; the shade thus obtained is a very dark brown.

Third Bath: Sulfate of iron, 3 per cent.; sulfate of copper, 1 per cent. Soak for one hour at 80°-90° C. Then wash in 0.5 per cent. soap solution at 60° and dry. A weak chloride bath intensifies the perfect black obtained.

For greys the same process is recommended, varying only the percentage of algarrobin. In Havana brown, by varying the percentage in the composition of the mordants, very pretty shades are obtained.

For silk and for animal fiber the process is the same as for wool.

The Coloring Material of Rice Leaves.

M. S. Kumagiri, of the Japanese Department of Agriculture, has succeeded in obtaining a deep purple dyestuff from the leaves or grass of the rice plant by subjecting the material to a special chemical treatment. Like litmus the new coloring material is affected by acids and is changed to a red. It is used successfully in analytical operations, and also for direct dyeing. As the leaves must be gathered before the rice is harvested, it is doubtful if the discovery is of much practical value.

The Use of Bacteria in the Preparation of Natural Indigo

We have had occasion to refer to the promising work now in progress in India, to establish upon a genuine scientific basis the treatment of the indigo plant, for the transformation of the indican present into indigo. The advance thus far made by those in charge of this important investigation, Mr. Hutchinson, the bacteriologist and Mr. Davies, the chemist, is outlined in a recent bulletin of the Pusa Research Institute, and is here briefly summarized:

The possibility of bacterial action was suggested by three facts. Firstly, the gas produced during the process of fermentation in the steeping vat varies in quantity and composition; secondly, chemical decomposition commences near the walls of the vat, and then spreads inwards, this suggesting that the presence of bacteria on the walls has something to do with the change; and, thirdly, there is a curious divergence in the yield, not only between different factories, but between vats of the same factory worked under apparently identical conditions, and in particular, when a new vat is brought into use it takes some days for it to reach the normal yield of the factory.

These observations suggested that the theory of transformation so far accepted, by which the main credit for the change was given to a constituent in the plant itself, was incomplete. The conversion of indican, the crude form of the dye, into indoxyl—which is subsequently converted into indigo by oxidation—appeared to depend in part on outside agencies, and laboratory researches showed this to be the case. It has now been established that bacterial action plays a considerable part in the process of change, being in fact essential to the extraction of the maximum yield of indigo. This is a discovery of great potential importance, for it at once supplies an explanation of, and promises a remedy to, the extraordinary differences in yield which occur in adjacent factories. In Bihar, for example, the variations are from one to several hundred per cent., and no satisfactory reason for their occurrence was previously advanced. It now appears to be certain that the high-yielding vats are equipped with a full stock of beneficial bacteria, while the low yielders are either inadequately stocked with these or contain actively hostile bacteria. Mr. Hutchinson has isolated the adverse bacteria, and also obtained pure cultures of several of the beneficent species, obtaining exact measurements of their indoxyl-producing powers. They exhibit considerable variation.

The introduction and propagation of friendly species can be effected in several ways. The steeping vats can be inoculated with pure cultures, or the multiplication of the beneficial organisms already present can be fostered by the provision of conditions favourable to their growth. Mr. Hutchinson believes that a combination of these two methods will prove the most satisfactory. At the same time the bacteria must be given fuller scope for their action. Being restricted to the walls and floor of the vat, their area of operations is limited, and if the vats are too large their productive powers fail to act on the more remote portions of the indican solution. It therefore appears desirable to adapt the vats so as to increase the ratio of wall surface to cubic contents. What the most efficient ratio is has still to be determined, but this is mainly a matter of experiment. It will certainly vary from factory to factory until the bacterial conditions are uniform. Again, the character of the wall surface is a factor of importance. A smooth cement wall is probably not the ideal surface, in which case a substitute has to be found. This also should soon be revealed by experiment. Once discovered, the practical benefits would be considerable, and quickly repay the producers for the necessary alterations.

A Foaming Process for Treating Textiles

Dr. René Clavel, of Basel, Switzerland, (Amer. Pat. 1,234,732, of July 31, 1917) describes a new process for treating textiles, such as silk, cotton or wool, either raw or finished, with foam. In earlier methods the foam was produced by boiling solutions of materials adapted to foam and aiding hereby, if desired, the conversion of the solutions into foam by injecting into the solutions air under pressure and in a state of fine division. More recently attempts have been made to work at lower temperatures by producing the foam under diminished atmospheric pressure, so that delicate textiles, particularly silk, might be successfully treated.

The processes, therefore, depend upon a supply of heat or steam or upon the action of a vacuum. The high temperature requires rapid working and the vacuum requires closed vessels.

By the present invention the production of foam is quite independent of the temperature of the foam bath, so that textiles which are sensitive to heat can be treated. The foam is produced by the introduction into the solution or liquid, of air, oxygen or other oxidizing, reducing or indifferent gases, under pressure, through finely porous bodies such as tubes or plates of unglazed earthenware, graphite or the like.

The method appears to be applicable with advantage in degumming and weighing silk, in degreasing and cleaning wool, and in numerous operations of dyeing, soaping, degreasing, fixing, mordanting, vat dyeing or developing dyes at any desired temperature.

Dye Extract Works in Jamaica.

Several local establishments in Kingston, Jamaica, for the production of logwood and similar extracts of dyewoods have been acquired by an American company, the United Dye Works Corporation, of which Joseph Baldwin, Jr., is president.

Dyeing by Means of Nitrous Acid and Metallic Salts

John Chester, of Saltaire, Eng. (Amer. Pat. 1,231,492, of June 26, 1917), has devised an improved process for dyeing wool and other animal substances by the use of nitrous acid and metallic salts. He claims to produce permanent colors on the materials in question by combining the substances producing the nitrous acid and the metallic salt in a single bath and by using the bath at a high temperature.

The following is an illustrative example:

Wool is treated in a bath composed of:

Sodium nitrite, 5% of the weight of the material to be dyed,

Commercial sulfuric acid, 5%,

Sodium bichromate, 2%, the whole being dissolved in a suitable quantity of water. The material is put into the bath when the latter is cold. The bath is gradually brought to the boiling point. In this case a brown color is produced. Sodium nitrite and sulfuric acid interact to form the necessary nitrous acid, as in all such operations.

A variation in the metallic salt causes a variation in the color produced. For instance, if copper sulfate be used instead of sodium bichromate, a brown, more reddish in character is produced.

It is claimed that dyeings effected in this manner are far more permanent than when the materials are first treated in a cold, nitrous acid bath and subsequently introduced into a bath containing a metallic salt.

Divi-Divi Extract.

A consular report states that Señor Antonio J. Salinas, holder of an exclusive privilege for the manufacture of tanning and dyeing extracts in Venezuela, has formed a company under the name of Salinas & Modiano for the extraction of tannic acid from the fruit of the divi-divi plant and its preparation in the form of powder or tablets. The company is located at Porlamar, Margarita. The process used is the invention of Señor Salinas. It is claimed that the tablets contain an average of 80 per cent of tannic acid.

The bulkiness of divi-divi relative to its actual value to the dyer and tanner has always caused freight to constitute the greater part of its delivery price. In times of tonnage scarcity this fact has rendered its exportation almost impossible.

Apparatus for Dyeing.

In a recent patent John H. Milner, of Huddersfield, Eng. (Amer. Pat. 1,230,198, of June 19, 1917), describes a new type of dyeing machine, applicable also for various processes of washing textiles. It utilizes the ordinary construction of upper and lower compartments, intermediate perforated plate, central circulating tube and steam supply main. In addition it combines an additional pipe adapted to introduce an auxiliary supply of air into the lower compartment, and to pass this upward, through the perforated plate, for the purpose of lifting the material to be dyed. The air supply is controlled by a steam-operated air injector having a branch connection from the steam supply main. The air supply and the ordinary steam supply can be operated separately or concurrently.

Natural Colors.

The following articles are of value to those especially interested in natural colors:

Note on the Coloring Matter of Red Torulae, A. Chaston Chapman, Chem. News, 1917, *115*, 135. The color is compared with carotin by spectrographic method, and is found not to be the same.

Detection of Catechu in Black Silk Dyeings, P. Weyrich, Faerb. Ztg., 1915, *26*, 317; J. S. C. I., 1916, *35*, 630.

The Dyeing Values of Some Indigenous (Indian) Dyestuffs, J. P. Srivastava, Agr. J. India (Special Indian Sci. Cong. No.), 1916, 53.

The Coloring Matter of Cane Juices, M. A. Schneller, La. Exp. Sta. Bull. No. 157, 1916.

Chlorophyll, G. Cusmano, Ann. Chim. Appl. (Rome), 1916, *5*, 97. A general review of the work on chlorophyll.

Toxicity of Carotin.

H. G. Wells and O. F. Hedenburg (J. Biol. Ch., 1916, *27*, 213) show that carotin is almost devoid of toxicity. Pigment carotin was prepared from fresh carrots and intraperitoneal and intradermic injections of an olive oil solution of the color were administered to guinea pigs, the larger doses being as much as would be contained in 200 kg. of flour.

Increased Cultivation of Indigo in Central America.

There is a notable increase in the area of land now devoted to the production of indigo in the Republic of Honduras. At the close of 1916 there were 1,088 tracts of land devoted to the cultivation of indigo in the Department of Intibuca alone. The total yield is estimated at 30,578 pounds. A marked increase in the cultivation of indigo is likewise reported from most of the frontier bordering on the Republic of San Salvador.

Hitherto Guatemala and especially San Salvador have been the chief sources of indigo in Central America. During the fiscal year 1916 the United States imported 85,000 pounds from San Salvador.

Climatic conditions in this region and also in southern Mexico are exceptionally favorable for the successful cultivation of the indigo plant. With helpful and favoring action on the part of the various governments the production of the natural dyestuff might become a much more valuable agricultural asset of Central America than has hitherto been the case.

MISCELLANEOUS

Outlook for the British Chemical Industry

By Prof. H. E. Armstrong

[The expansion of our American chemical industry in general, and especially of our coal-tar chemical industry, is following lines closely parallel to those along which the British industry is moving. The obstacles to be overcome are mainly the same in both lands. Those laboring in the United States, to liberate us from any dependence, in the future, on German colors and drugs, will find abundant food for reflection and suggestion in the following vigorour portrayal of the British chemical outlook, recently contributed to the London Times by Professor H. E. Armstrong, who stands in the forefront of English chemists, and is constantly consulted by the Imperial authorities on chemical problems of national importance.—Ed.]

One of the most striking results of the war is the advance of the chemist into public favor. Before it, he was scarce considered except as the drug dispenser, though there was a vague idea abroad, and a very wrong one, that he was a person who could analyse and find out of what anything put into his hands was made; in fact, he was either thought nothing of or his powers were vastly overrated. The first thing to be done when the war is over will be to give him the status he has won: by Act of Parliament to recognize that he alone has the right to be called chemist, so that he may be distinguished from the pharmacist.

A recent French writer on the wonderful development of the German chemical industry, particularly in connection with the production of materials required for the manufacture of explosives, speaks of the chemist as having saved Germany. At the outbreak of war her chemical factories were so fully organized that she was able, if not to make all that was required, at once to take the necessary developments in hand.

After the Marne, very large Government subsidies were forthcoming to aid the extension of factories for the production of ammonia and nitric acid, the basic substances of the high explosives industry, by purely artificial processes. The figures given of the outputs achieved approach the fabulous. Deprived as she has been of raw materials, the manner in which Germany has mastered the difficulties is very wonderful. When, if ever, the story is fully told, it will probably be the most astonishing revelation conceivable of the power that man has achieved through science—both for evil and for good. When viewed in proper historical perspective, it must afford lessons of a development of man's command over Nature which will be altogether amazing in extent and variety.

But if the chemists—associated necessarily with the engineers—have saved Germany, in the sense of enabling her to wreak her foul purpose upon those whom she has made her foes, the latter, in turn, have been able to make use of their services in their defence and in a far higher degree. Our advance within a couple of years is comparable almost, it has been said, with that made by Germany during 40 years. We had made scarcely any preparation, and yet it is now admitted that, in not a few respects, we are in advance of her. It may well be imagined that one of her greatest regrets will be that she has made us realize what we can do if forced into action. We were quietly asleep in the mountains, and had matters remained as they were, we should have awakened only to find her in possession of the fertile plains.

Though not an "organizable" people, we have a far greater innate gift of organizing than the Germans. Under compulsion, we have at last allowed ourselves to be organized. The conservatism, which in ordinary times has made us chary of adventure, and checked experiment, has necessarily been waved aside, though not always with the requisite promptness. Even now we lack outlook and a saving grace of modesty. As shown most clearly in the recent Dardanelles report, we still fight shy of the expert, and our self-appointed, would-be leaders too often are the last to appreciate their inability to grapple with the problems they are called upon to solve. The country suffers most, perhaps, from inability to appreciate its ignorance and its consequent impotence to face the complex issues of our modern civilization with understanding. This is our most vulnerable spot, one that ultimate success may lead us still to overlook.

The question of questions concerning our future is whether we shall have learned our lesson sufficiently not to return to our old slothful, ignorant ways, especially whether we shall be willing to work together. The augurs seem to speak hopefully, though they warn us against any slackening of effort.

Agriculture.

To refer first to our chief chemical industry. It is recognized that the greatest of all the world's industries is agriculture, especially if it be held to include forestry, yet few realize that agriculture is, in large measure, a chemical industry of a quite special character and one which presents altogether peculiar difficulties, concerned as it is with the processes of life. No one who has not a very thorough and broad knowledge of chemistry can have real feeling with regard to the problems of modern agriculture; though the phenomena to be interpreted are in no way exclusively chemical, chemical principles are everywhere in operation.

Of all Government Departments, the Board of Agriculture hitherto has been one of the least venturous, perhaps the most difficult to move. It has lacked ideas and ideals, largely through inability to grasp and understand the technical problems of the industry. It has mainly served administrative ends.

In these circumstances, the recent appointment of Mr. A. D. Hall as chief permanent official of the Board, must rank as a step of high importance. It is the first time, apparently, that an actual scientific expert, a Fellow of the Royal Society, through the force of his work, has been appointed to such an office, without reference to Civil Service or political considerations, solely in the interests of efficiency.

Manufacturing Industry.

Turning to manufactures, the future of the chemical industry is intimately bound up with that of British industry as a whole, in particular that of the great textile trade, which is not only dependent upon dyestuffs but is also the chief consumer of so-called heavy chemicals—of alkali, of soap, of acids, and of bleaching powder. The prosperity of the industry can be the consequence only of a general industrial prosperity.

The success of the chemical industry will depend upon the development of economical methods in every branch of its work. The disastrous internecine competition of the past must be eliminated and for it must be substituted an effective co-operation; not only must the highest technical efficiency be secured through wise and generous management, but the ever-present need for continued development must be kept constantly in mind.

It is beyond question that we shall be called upon to face highly organized competition from every quarter—Germany has made the whole world live once more. This can only be met by an equal, if not a superior, degree of technical organization on our part. Whether traders shall be assisted by any protective system is not a suitable subject for this article, nor one with which the writer can deal; yet it is impossible to overlook the fact that, in many quarters, the view prevails that the necessary development cannot be secured without State assistance, at least during the early stages.

Although certain special branches have been highly prosperous, it is beyond question that the chemical industry has languished in this country largely because it has been in a disorganized condition; many reasons have been assigned to explain the failure, but it is clear, particularly if the cases of success be analyzed, that they are all included in this general statement.

Using the term in the broad sense in which the engineering or textile industries are referred to, it is hardly possible to speak of the existence of a chemical industry. The industry has never been in a position to represent its requirements and views in any collective form—a political demonstration such as the textile industry has made recently is inconceivable.

The war has played the part of the fairy prince in leading us to recognize Cinderella's virtue. For the first time, chemical industry is regarded as of national importance—as a primary factor of national safety.

Union or Disaster.

But it must none the less work out its own salvation from within—it must develop ideals and ideas—it must become progressive; above all, it must present a united front. The chemical industry has too long suffered from the inability of firms to work together for any common end. It cannot be insisted too strongly that unless the tendency can be overcome, which so unhappily exists in this country, of regarding all matters from a purely personal point of view, of allowing entirely personal proclivities and considerations, likes and dislikes, and jealousies, to prevail, there can be no success in the future. The recent formation of an Association of Chemical Manufacturers is therefore a step of outstanding importance.

It is to be hoped that ere long the new Association will be able to work in effective conjunction with the Society of Chemical Industry, and that the two bodies will develop complementary activities. The Society has failed hitherto to exert any real influence on chemical industry, and it has been far too much under academic control. But it has never been supported in any proper way by the higher industrial element, one chief reason being that this element itself was without corporate existence and often too narrowly commercialized to appreciate even its own requirements. The coming expansion of the industry must carry with it recognition of the value of science and automatically determine the development of the Society's activity and sphere of usefulness.

But a far more extensive organization of the forces of chemical science must be brought about in the near future if these are to be utilized with effect in the service of the nation. A multitude of special societies now exist representative of a variety of special interests, but largely composed of the same men. The system is wasteful in every respect. It neither serves to promote fellowship nor to encourage breadth of outlook. On the contrary, it is a direct incentive to an undesirable degree of specialization; it only ministers to our very human tendency to form cliques within each of which a set of men can assume importance. We must hope that we shall have learned sufficient wisdom through the war to bring all agencies together which can contribute to the development of chemistry either as an abstract science or in its technical applications.

The Day of the Expert.

Complete organization combined with breadth of outlook in every direction are the essential conditions of future success. Sound finance, a bold and conciliatory sales policy, intelligent buying on a large scale, first-class commercial representation, are all requirements of fundamental importance, which are more or less commonly recognized. But of equal importance, though too often neglected, are the works requirements: the need of a staff of special efficiency ,including an adequate research department, not forgetting also the labor element. Success necessarily involves a progressive outlook. In these days, to stand still is to go back. In future, the technical man must be given a real voice in the commercial control of the works. Our failure to recognize this need is more than anything else perhaps at the root of the errors of the past. Chemistry as a science, and the problems of manufacturing chemistry in particular, demand for their understanding a point of view, a mental attitude and an experience which are foreign to the community at large, and cannot, as a rule, be acquired by commercial men; but it is well within the mental grasp of the man trained to understand scientific problems also to appreciate the problems which the commercial and industrial control of works presents. The main cause of the phenomenal success of German chemical industry has been the admission of the technical experts to a full share in the management; chemist, commercial man, and engineer have been treated alike and given co-ordinate rank. Such must be the case here, if we are to succeed.

The larger firms are already alive to the value of co-operation, but this is in no way recognized at present by the smaller. If wasteful internal competition in the manufacture of substances of which but limited quantities are required should continue, it is clear that no form of protection will enable makers to meet the competition of foreign manufacturers operating on a much larger scale with more perfect plant. Charges for labor and establishment make up so great a proportion of the cost that the manufacture of, say, four times the quantity of an article may have the effect of reducing cost to one-half or even less, in which case a 100 per cent. tariff would be the least that would be effective. The salts of bismuth may be taken as an illustration. Although largely used in medicine, the quantity required in this country is well under two tons per week, a quantity which could easily be manufactured in one small works. In point of fact, the manufacture is now distributed over a considerable number of works, perhaps 10. If only a single works were in operation it would be possible to cut down the supervising staff, the analytical work, and the cost of maintaining plant, labor-saving devices would be worth introducing which cannot now come under consideration, by-products might be utilized, and much waste prevented by proper association of the work with other branches of industry.

Only a large firm can afford the expense of a competent research staff and of the many specialists required under modern conditions. Savings of a fraction of a penny per pound, which seem of no importance to the small man, mean many thousands to his competitor who makes on the large scale. It cannot be economy for 40 firms each to make 40 products at 40 different works—but such has been our method. In some way they must combine to close the older works and specialize by small firms making only a few products at the remainder.

Much more than is commonly supposed has been done here to manufacture the more valuable chemicals; alkaloids, for example, such as atropine, emetine, etc. But in future some more definite national policy must be developed if the industry is to be maintained and enlarged.

Supplies of Drugs.

Better control of raw materials could be secured by co-operation among buyers, as well as by assistance from Government and Consular agents and Government Departments generally.

What the Dutch have done in Java with respect to supplies of cocoa leaves for the production of cocaine and cinchona bark for the production of quinine, England might do in her various colonies and so provide most, if not all, of the raw materials that are required, though we must take care that foreign competitors do not corner these.

When in Java in the autumn of 1914, at the wonderful botanic garden at Buitzenzorg, and elsewhere in the island, the writer had full opportunity of appreciating Dutch economic organization and of contrasting it with our own half-hearted unsystematic measures in the East. But we have made a great advance in the interval.

India has long since met her own needs in quinine. The writer can testify from his inspection of the factory near Darjeeling that the manufacture is carried on in a most efficient manner; the plantations are now becoming so extended that, at no distant date, it should be possible to produce in India all the quinine that is required by the Empire.

The opium produced in India was long regarded as unsuitable for pharmaceutical purposes and very little of it was used, but it is now being exclusively used by manufacturers for the production of morphine. It is true it is inferior to the Turkish and Persian varieties in the amount it contains of this alkaloid, but work is now being carried on to produce an improved material, and there can be little doubt that success will be secured, such is the control we now have of problems of the kind.

Vigorous action is also being taken, under the auspices of the Government of India, to promote a resuscitation of the natural Indigo industry, and there is good reason to believe that this will be possible, if complete cooperation can be secured of all who are concerned. Not a few other illustrations could be given.

There are not a few successful firms in the country as completely organized as any to be met with on the Continent, and these have quietly done their work in the past without particular advertisement. It is recognized, however, that a much wider field has now to be covered, and that, in particular, those branches must be developed in which we were at such a disadvantage. But a new spirit is alive in the country. Great developments have been brought about under the exigencies of war, as those of us who have been privileged to see the new works erected of late can testify. The value of experiment is now understood in a way that it never was before. It is realized that if you are forced to meet a situation and know what you want to do, it is usually possible to effect your purpose; and the value of ideas and of opportunity to test ideas in practice is at last recognized.

The great want of industry in future will be skilled men and gentlemen. It must attract to its ranks on the technical side—the men of business aptitude will take their place naturally—the best type of university graduate. The literary professions and the civil service must no longer have the monopoly of the best brains. The leaders of science must preach the dignity of industry—its value as national service. Now that business men have at last gained admission to the Ministry, it is clear that commerce and industry will secure due recognition at the hands of the nation; some day even science may be considered competent to help.

Progress of the Coal-Tar Chemical Industry in Canada

Not only in the United States, but also in Canada, the movement to attain independence in the production of coal-tar chemicals is gaining increased momentum. According to the Toronto Globe, aspirin, phenacetin and acetic and carbolic acids are being produced and sold as home-made products for home consumption. For the first time moth balls are being manufactured in Toronto. Aspirin, formerly imported from Germany, is produced so successfully that prices, which increased fourfold through the stoppage of German shipments, have been greatly reduced. In 1914 phenacetin sold in Canada for 80c a lb. In 1915 the price soared to $41 a lb., but it is now back to $21. Carbolic acid, which rose to prohibitive prices, has been reduced by discoveries and experience in manufacture. Quotations for salicylic acid are 360 per cent. below extreme war prices. All qualities of acetic acids are now made, and for the first time, glacial acetic acid—99 per cent. pure—has been produced in Canada. before the war at 22c, rose to $4.25, but through man- Later the price was advanced to $12, but it is now down to $6 in consequence of successful home production. Naphthalene rose from 2½c a lb. to 15c, but is now produced in Toronto at 8c. Salicylic acid sold before the war at 22c, rose to $4.25, but through manufacture on this side of the Atlantic, is now obtainable at 80c a lb. It is believed that producers and chemists on this continent who have made heavy expenditure for research and machinery will hold much of the trade they have secured, even against European competition, when peace is restored.

Improved Method of Making Sodium Phenate.

W. Everitt & Co., Ltd., and W. Everitt, of Southall, Middlesex, Eng. (Brit. Pat. 105,612, of 1916) have perfected a process for manufacturing dry, powdered sodium phenate, the details of which are as follows: Equivalent amounts of powdered sodium hydroxide and phenol mixed with 5 per cent. of sodium sulfite are heated at 260° to 280° C. The operation is carried on in a ball-mill under constant agitation. Steam is evolved during the reaction, at the close of which the product is allowed to cool in vacuum. It can easily be removed in the form of a dry powder.

Standards of Colors

The following recent papers are of value to all interested in matching and comparing colors:

Color Standards and Colorimetric Assays, H. V. Arny and C. H. Ring, J. Ind. Eng. Ch., 1916; *8,309;* Oil and Col. Tr. J., 1917, *51,* 1055. The author uses combinations of Co, Fe, Cu, Mn, etc., for color comparisons.

A Numerical Expression for Color as given by the Ives Tint Photometer, O. Kress and G. C. McNaughton, J. Ind. Eng. Ch., 1916, *8,* 711.

Color Matching Unit (A Lamp), St. Louis Brass Mfg. Co., St. Louis, Elect. World, 1917, *69,* 731. This lamp called the "Spectrolyte" uses a 60 watt Mazda lamp. Light rays are modified by reflection, not by transmission.

A New Colorimeter, C. F. Sammet, J. Ind. Eng. Ch., 1916, *8,* 519.

Stereosopic Colors, M. Lukiesch, J. Frank. Inst., 1917, *183,* 773. On viewing colored objects in the same plane as in the projected image of a lantern slide, the different colors do not always appear to be in the same plane. This note describes some preliminary measurements of the magnitude of this stereoscopic effect.

Measuring the Color of Papers, Numerical Expression for Color, Ives Tintometer, O. Kress and G. C. McNaughton, Paper, 1917, *19,* 15.

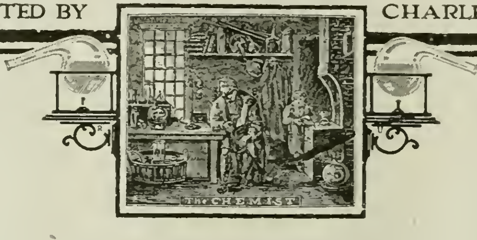
CHEMICAL INVESTIGATION
EFFICIENCY & CONTROL

CONDUCTED BY CHARLES B. DAVIS. F.C.S.



ALL classes of work covered by the following subjects will be done for readers of "The Chemical Engineer" through this department by Mr. Davis: Special research of every description; analysis and reproduction of any commercial product; prevention of waste and utilization of by-products on the most economical basis; valuation of raw materials; food analysis, and disputed points in regard to adulteration, labeling, and the enforcement of pure food laws; bacteriological and enzymatic examinations, including fermentation tests, pure yeast cultures, beverages of all kinds; development of chemical inventions and industrial processes; examinations and advice on special machinery.

Inquiries of a minor character will be answered on this page, while major matters involving personal investigations, analyses, etc., will, if desired, be treated confidentially through the mails. All questions, materials for analysis, or letters leading to the opening of negotiations for special work will receive prompt attention if addressed to

CHARLES B. DAVIS,
Care of "The Chemical Engineer," 118 East 28th Street,
New York City.

A. W. T. If you desire to reduce the time of exposure in taking your X-Ray photographs, you can do so by using two intensifing screens on either side of your sensitive plate or film, the one nearer the X-Ray tube being of crystalline calcium tungstate, more transparent to X-Ray, and the other one being of the semi-crystalline salt, much less transparent to X-Ray.

I trust this will remove the difficulties you are now experiencing.

F. A. W. The explosive known as "Trinitrotoluol" is a slightly yellow, fine and crystalline powder. You had better forward me a sample of your product so I may submit it to tests in order to ascertain whether or not it comes up to the standard required by the U. S. Navy for a refined Grade "A" material.

L. C. I received the sample of buttermilk and after careful chemical analysis, find it to be a product of Bulgarian bacillus and not the old fashioned buttermilk that has been churned. Real buttermilk is not made artificially, therefore when made from the above bacillus it is a direct violation of the State and National food laws, if sold under the name of buttermilk.

W. W. H. The wine you forwarded last week for analysis has been found to contain artificial coloring matter in the form of an acid, namely, red analin dye. If you fail to mention its presence on the label you will be subjected to a fine.

F. T. S.—The preliminary investigations of your hair tonic and greaseless face cream show them to consist of the following ingredients: Hair tonic—Terebene, sulphur, borax and lavender water. Greaseless face cream—Almond oil, spermaceti, white wax and geranium oil. As requested by you, I am mailing you the complete analysis, giving the exact quantity of each constituent, together with working formulae for their preparation.

C. M.—The solubility of calcium sulphite ($CaSO_3.2H_2O$) in 15% cane sugar solution at 30° C. is 103 mgr. per litre. This amount decreases to 11 mgr. as the temperature is increased to the boiling point of water.

K. L. S.—Your letter together with sample of fumigant has been received and wish to state that its chemical analysis shows it to be Para-Dichloro-Benzene ($C_6H_4Cl_2$).

It possesses a weak ether-like odor, volatile in air and has a melting point of 53.0° C., and a molecular weight of 146.952.

W. A. F.—Regarding the dying of your wool with the coloring matter you have enclosed, I advise you to use the following method:

Sulphuric acid	1.5%
Coloring	3.5%
Glaubers salts	2.0%

Boil together and strain in bath. Start bath at 170°, raise to 190° slowly, wash in warm water.

S. R. D.—As I have mentioned many times in these columns, coal having low calorific or heating value not only clogs the grates and eventually ruins them, but its purchase at even low price is anything but economical. Soft coals having a heating value of 12,000.0 B.T.U. like those you have just forwarded me for analysis are far below the average.

Charles B. Davis.

Those whose inquiries to this department have not as yet received attention must bear in mind that unless replies by mail are specifically requested, communications can only be considered in the order of their receipt.—Editor.

ULTRA VIOLET LIGHT

Its Application in Chemical Arts

By Carleton Ellis and A. A. Wells.*

This Is the Seventh Installment of an Article Dealing with an Investigation Conducted by the Writers into the Possible Applications of Ultra Violet Light. The Present Paper Continues the Discussion of Various Forms of Apparatus Employed for the Sterilization of Transparent and Opaque Liquids, Emulsions, Municipal Water Supplies, Etc., by Means of Its Rays. Part VIII Will Appear in the Next Issue.

PART VII

Sterilization of Liquids—Continued.

Henri, Helbronner and von Recklinghausen (U. S. Patent 1,091,221, March 24, 1914) describe an apparatus for the sterilization of water and other similar liquids, which consists of a chamber filled with the liquid to be sterilized, in which chamber is located the source of ultra violet rays. Inasmuch as the efficiency of the ultra-violet lamp depends upon the temperature, the lamp itself is surrounded by a containing vessel made of quartz or other similar material which is exhausted to a very high vacuum in order to obviate the absorption of the ultra violet rays by the air which would normally be contained in the enclosing vessel.

An apparatus for treating liquids which are practically transparent to the ultra violet rays has been proposed by Henri, Helbronner and von Recklinghausen (U. S. Patent 1,132,266, March 16, 1915), who use a treating chamber located more or less radially about the lamp and having baffles which radiate toward the lamp, thus producing an apparatus in which there are no shadows. The liquid to be sterilized is passed in at one end of the apparatus and flows back and forth around the baffles, in this manner being agitated and thoroughly exposed to the action of the light.

Centrifugal Apparatus.

In another process for sterilizing liquids such as water, Henri, Helbronner and von Recklinghausen (U. S. Patent 1,140,819, May 25, 1915) describe the use of an apparatus which consists of a cylinder to contain the liquid to be sterilized, through the center of which is passed a rod serving as a support for the ultra violet lamps. The two types of apparatus are indicated, in one of which, the chamber itself is rotated at such a speed that the water therein will be thrown to the sides, thereby forming a hollow space in the center. The lamp or lamps are situated in this central space. This arrangement prevents the cooling of the lamps by contact with the liquid. As the chamber itself is air tight, the vacant space surrounding the lamp would be under somewhat reduced pressure, thus minimizing absorption of ultra violet rays by the air. In the other case, the chamber itself is stationary but a propeller is placed therein which when rotated throws the liquid, undergoing sterilization, to the outside walls. If desired, air or an inert gas may be admitted to the vacant space about the lamp.

Rotary Funnel Apparatus.

A funnel shaped apparatus, also by Henri, Helbronner and von Recklinghausen (U. S. Patents 1,118,006, November 24, 1914, and 1,132,265, March 16, 1915) for sterilizing milk or other liquids. In case the liquid is transparent, such as water, it is passed in a comparatively thick film along the sides of the chamber, which is rapidly rotated. The liquid is admitted at the bottom and the effect of rotation is to cause it to run up the sides and over the top into a suitable receiver. In case the liquid is rather opaque, such as milk or emulsions, the walls of the sterilizing chamber are corrugated. As the container is rotated, the liquid slowly climbs to the top, being spread out in very thin layers as it passes over the corrugations, thus exposing the fluid in an efficient manner to the action of the light. Another modification of the same apparatus consists in passing a vigorous stream of air through the liquid, causing it to be strongly agitated and be thrown up from the surface of the liquid in the form of spray. On account of the extremely fine division of the particles in this spray, sterilization is claimed to be very efficient. The current of air also serves to keep the liquid cool and to remove any ozone which is formed and which in certain instances, such as in the case of milk, would cause a disagreeable flavor. Other modifications, such as spraying water on the outside of the container to reduce the temperature and of inverting the funnel and allowing the liquid to flow on the outside into a receiving vessel are also described. In this latter case, the source of light is located outside of the sterilizing chamber.

In still another apparatus for sterilizing liquids, von Recklinghausen (U. S. Patent 1,193,209, August 1, 1916; J. S. C. I., 1916, 976) proposes the use of a small corrugated chamber located above an ultra violet lamp. The liquid to be sterilized flows down the corrugated walls of the vessel and thus becomes sterilized by the action of the light. Methods of control of operation of the lamp and of the flow of water through the apparatus are given; also a method for automatically emptying the device in case the current should be cut off. The temperature of the operation is controlled by cooling with water.

In apparatus of the type where a mercury vapor lamp, surrounded by a quartz chamber, is immersed in the liquid to be treated, a ball-float or similar device is proposed by Helbronner and von Hecklinghausen (British Patent 4,895, Feb. 27, 1911) so that the operation of the lamp is prevented until the liquid rises to such a level in the tank, in which the sterilizing operation takes place, that the lamp is completely immersed in the liquid. The ball-float may be fitted in a small chamber on the pipe supplying the liquid to the tank containing the lamp.

A form of apparatus in which the lamp emitting the ultra violet rays is suspended above a tank containing the water is also described by Helbronner and von Recklinghausen (British Patent 24,632, Oct. 28, 1912). A helical quartz tube is mounted within the tank with its upper end just below the surface of the water and the lower end passes through the bottom of the tank. The upper layer of water, which is sterilized by the rays, passes into the helical tube and is discharged through a valve at the lower end. When the apparatus has not been used for some time, this valve may be closed for a short time until the tank is filled and the water overflows, carrying with it floating impurities.

Control Devices.

Where the liquid is admitted to the sterilizing chamber through a valve which is operated by an electromagnet in series with the lamp Helbronner and von Recklinghausen (British Patent 21,829, May 1, 1911) suggest the use of an auxilliary valve so that any liquid leaking through the main valve when the latter closes owing to the lamp being extinguished, is conducted directly to a waste pipe and is thus prevented from entering the sterilizing chamber.

Von Recklinghausen (U. S. Patent 1,190,609, July 11, 1916) describes an apparatus for the treatment of large volumes of water for sterilization. The container for the water consists of a large tank or chamber with an ultra violet lamp bent in the shape of a U attached to one side and extending into the interior. The lamp is protected from actual contact with the water by a quartz tube. The necessary electrical appliances, such as switches and rheostats, are enclosed in a receptacle attached to the water container adjacent to the lamp. In case of breakage of the protecting tube, thus allowing the water to escape, means are provided for conveying this water away before it has an opportunity to damage the electrical appliances. A number of modifications of the apparatus are shown.

Helbronner and von Recklinghausen (French Patent 415,842, April 20, 1910) describe several devices for sterilizing liquids which ensure that the liquid under treatment shall present a perfectly smooth surface while it is being subjected to the action of ultra violet rays proceeding from a mercury vapor lamp. This object is attained by passing the liquid, during treatment, through a number of rectangular tubes or around partition plates reaching alternately nearly to the top and bottom of the vessel. Tubes of various sizes may be placed in the vessel in order to equalize the velocities of the different currents in the liquid. The tubes may be inclined, having the inlet ends slightly above the surface of the liquid.

Removing Dissolved Air.

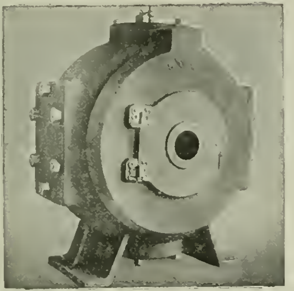
A cylinder provided with a piston for forcing the liquid through the treating vessel is also suggested by Helbronner and von Recklinghausen (British Patent 8,158, of 1911). Compressed air is admitted below the piston so as to cause it to rise to the top of the cylinder, thus allowing the liquid to flow into the part of the cylinder below the piston. When compressed air is admitted above the piston, the liquid is forced out into pipes which conduct it to the treating chambers. Another apparatus for removing dissolved air from the liquid previous to treatment with ultra violet rays is described, which consists of a rotating bell-shaped vessel mounted in a chamber. The liquid is allowed to flow over the outer surface of the vessel while the air is exhausted from the chamber.

Rotary Chamber.

Triquet (J. S. C. I., 1912, 43, U. S. Patent 1,030,692, June 25, 1912) describes an apparatus for sterilizing water which consists of a vessel flanged at both ends and having several flanged openings on the sides. The end flanges are connected to reducing chambers which in turn are connected by means of stuffing boxes to the water inlet and outlet pipes, thus making the sterilizing chamber rotable. The side flanges connect to ducts within the chamber in which are mounted quartz mercury vapor arc lamps, the mercury chambers of which are outside of the sterilizing chamber. In order to tilt the lamps in starting, the whole body of the sterilizing chamber is rotated. The lamp chambers are tightly closed by covers fastened into place with clamps and set screws.

Opaque Liquids.

Von Recklinghausen sterilizes opaque liquids (Chem. Abs. 1916, 649, U. S. Patent 1,165,921, Dec. 28, 1915) by means of an apparatus which exposes the liquid in a thin film, formed by passing the liquid between two plates spaced a short distance apart. The upper plate is composed of quartz or some other ultra violet transparent material. The plates are held in place by thin sheets of tinfoil. The liquid to be sterilized is held in a container located somewhat above the treating chamber, thus causing a constant pressure and therefore a constant flow of liquid through the sterilizing chamber. A device for automatically cutting off the apparatus in case it should become clogged by small particles of material, for example particles of butter, is described. This device operates to ring a bell to warn the attendant or the lamp itself may be cut off. Two modifications are shown by von Recklinghausen, one of which consists of a balance, one end containing a vessel to receive the sterilized material, while in the other end a similar vessel is placed which receives a stream of water having its flow regulated at the same rate as the material from the sterilizer. In case the weight of water exceeds the weight of milk or other liquid undergoing sterilization, a short circuit is formed and either the operator is warned by means of a bell or the lamp is shut off. In another case the receiving vessel is located at such a distance from the outlet from the sterilizing chamber that the stream of liquid will flow from the sterilizer, at a predetermined rate, into the receiving vessel. In case the flow becomes retarded not all of the liquid will enter the receiver. A portion of it will fall upon an inclined electrode having a short gap so that when the liquid flows across this space it will cause a short circuit, thus warning the operator.



Small Pressure Type Sterilizer for Use in Homes, Small Office Buildings, Hotels and Small Manufacturing Plants.

(Courtesy R. U. V. Co., New York.)

Henri, Helbronner and von Recklinghausen (U. S. Patent 1,145,140, July 6, 1915) propose the following form of apparatus for the treatment of deeply colored or opaque liquids or emulsions which normally are rather difficult to sterilize efficiently. The apparatus consists of a series of narrow chambers enclosing an ultra violet lamp; the sides of the chambers facing the light being made of quartz plates. The plates are spaced apart with paper, rubber, etc., thus forming a very narrow chamber through which the liquid flows during the process of sterilization. In one instance these chambers are mounted so that they may be rotated about the source of light, thus exposing all surfaces uniformly. In order to prevent the liquid, undergoing sterilization, from becoming too hot, the series of chambers may be arranged to form the walls of a receptacle, which is filled with water, or a thin film of water may be sprayed over the surface exposed to the action of the light. It is stated that since water is more transparent to ultra violet rays than air, better efficiency is obtained by having the space between the lamp and the sterilizing chamber filled with water than is the case when air has free access.

Automatic Distance Maintaining Device.

In another apparatus of Helbronner and von Recklinghausen (British Patents 28,067, Dec. 1, 1909, and 25,883, Jan. 24, 1910) the source of the ultra violet rays is supported by a float mechanism (floats operating in chembers connected with the main conduit), so that a constant distance between the surface of the liquid and the source of the rays is automatically maintained. The lamp may also be mounted in a closed container fixed in a constant position above the liquid, the surface of which is automatically maintained at a definite level by means of a float valve capable of admitting air either under compression or at atmospheric pressure.

In still another apparatus described by Helbronner and von Recklinghausen (First Addition to French Patent 403,947, June 11, 1909; J. S. C. I., 1910, 107) the lamp which is employed is enclosed in a chamber constructed of material which will transmit ultra violet rays and from which the air is exhausted. This chamber has two widened portions for receiving the ends of the lamp, while its central part is tubular and may be of circular, triangular or hexagonal cross section. The liquid may be treated under pressure by passing it through a tank provided with baffle plates which direct the current of water around the chamber. The lamp employed (First Addition, to French Patent 424,369, March 12, 1910; J. S. C. I., 1911, 978) may also be contained in a chamber shaped so as to receive the wide ends of the lamp, the central portion of the vessel being tubular and capable of transmitting ultra violet rays. This tubular portion may also be of hexagonal or triangular cross-section. The lamp may be located in a tubular chamber fitted in a tank containing partitions which direct the current of liquid below and then above the lamp.

A sterilizing apparatus proposed by von Recklinghausen, Helbronner and Henri (U. S. Patent 1,196,481, Aug. 28, 1916; J. S. C. I., 1916, 1079) consists of a mercury vapor arc lamp which has an enlarged nonluminous portion at one end, containing both electrodes, and a narrow luminous portion which is placed in the side of the sterilizing chamber so that the narrow portion projects into a tube in the chamber while the non-luminous part of the tube remains outside.

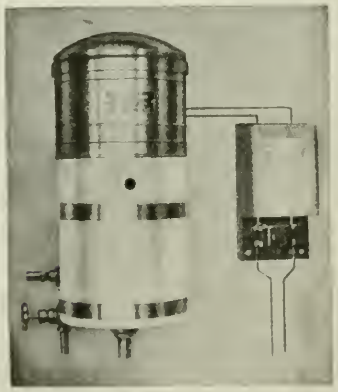
Effect of Shape of Lamp.

It is stated by von Recklinghausen, Helbronner and Henri (U. S. Patent 1,176,481, Aug. 29, 1916) that in a mercury vapor lamp of given dimensions and a constant amount of electrical energy there exists a definite relation between the amount of ultra violet rays produced and the amount of luminous radiation. If, however, any of the above conditions are changed, the ratio between the violet and luminous portions of the radiations will be altered. It is stated that this is probably due somewhat to the temperature of the lamp as the ultra violet rays are increased in a given length of tube as the temperature rises. By constructing the mercury vapor chamber in the form of a U the two electrodes are brought close together and the heat radiations from one help to heat the other, thus raising the amount of ultra violet rays produced in proportion to the current consumed. In the construction of lamps of the U shape, there is a tendency for that portion of the quartz tube at the bend to deteriorate or become opaque due to the fact that in making this bend the center of the tube is not followed. It is proposed to reinforce these U-shaped tubes on the inside of the bend, thereby prolonging their life.

In a form of lamp devised by Helbronner and von Recklinghausen (British Patent 14,129, June 10, 1910) the lamp proper is surrounded by a quartz or silica envelope. The air is completely exhausted from the space between the lamp and the outer tube or envelope so that, when the apparatus is immersed in a liquid, radiation of heat from the lamp is prevented, while the normal working of the lamp is not affected. The wires conducting the current to the lamp pass through the walls of the envelope. In one form, only the straight tube between the two bulbs is surrounded by an outer jacket.

Powerful Source of Ultra Violet Light.

A type of powerful ultra violet lamp described by Helbronner and von Recklinghausen (Comptes. rend., 1912, 155, 852,854) consists of a quart U-tube the sides of which nearly touch one another. The diameter of the tubing is 14 mm. and the length of the sides 160 mm. The two mercury electrodes are side by side. The lamp takes a current of 500 volts, with a difference of potential between the electrodes of 375-390 volts, and with an intensity of 3 amperes. The illuminating power perpendicular to the axis is 8,000 candles. Chemical reactions brought about by ultra violet rays are claimed to be very greatly accelerated by the use of this lamp. For sterilizing large quantities of water the lamp is placed in a cylinder of transparent quartz; this is placed in the center of the sterilizing tank and by a series of baffles the water is made to circulate round the cylinder. In this way the lamp burns as in air, and the utilization of the rays is complete. As to the life of this lamp, Helbronner and von Recklinghausen claim that an installation of 8 amperes has been used 1,200 hours without change, the strength of the rays being tested each day by the rapidity of the blackening of silver citrate paper when exposed to them.



Small Gravity Sterilizer Particularly Applicable to Homes, Laboratories and Small Bottlers.

(Courtesy R. U. V. Co. New York)

Sterilization Investigations by Spencer.

Tests of ultra violet ray apparatus for the sterilization of water have been conducted by Spencer (Engineering and Contracting, 1917, 256).

A gravity and a pressure type of mercury vapor arc lamp apparatus were tested. In the gravity type the lamp is suspended in a baffled treatment chamber a few inches above the surface of the water, which in a thin film is exposed twice during its passage by the lamp. This type is operated at 110 volts and has a rated capacity of 120 gal. per hour.

Gravity Type Apparatus for Swimming Pools, Also Used by Brewers, Bottlers, Ice Manufacturers, Etc.

(Courtesy R. U. V. Co., New York.)

The pressure type consists of a cast iron cylindrical shell with a quartz tube through its axis and containing an arrangement of baffle plates for the same purpose as those in the gravity type. The lamp is inserted within the axial quartz tube. A 220-volt lamp is required to produce a sufficient amount of ultra violet rays for treating 750 gal. of water per hour, the rated capacity.

Usually a fluctuation in voltage of 10 per cent. or over is sufficient to extinguish the light. To prevent the passage of untreated water, each apparatus is provided with an automatic electrical arrangement controlling valves which will prevent the flow of water until the temperature of the lamp has risen sufficiently to produce an abundance of ultra violet rays and which will cut it off when for any reason the light goes out.

Each apparatus was operated in connection with a rapid sand pressure filter which clarified the water just before it entered the light chamber. It was at this point that all the raw water control samples were taken. In order to artificially contaminate the water the alum shunt-feed box on the filter was kept filled with rich broth cultures of B. coli and other bacteria. By this means enormous quantities of all kinds of organisms could be fed to the filter, which allowed nearly all to pass through to the ultra violet ray apparatus after the sand bed had once become thoroughly saturated with them. The raw water contained many more times B. coli than one ever finds in the worst drinking water.

The vast majority of all samples were collected while the apparatus was being operated in excess of its rated capacity.

Small Gravity Type Apparatus.

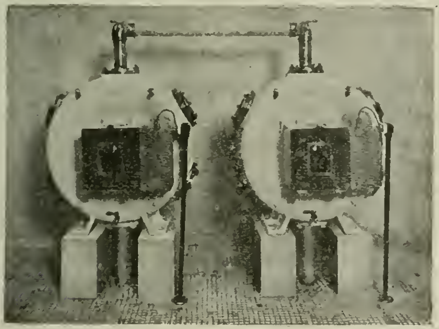
(Capacity, 120 gal. per hour.)

The following table includes a total of 142 samples, taken on seventeen different days during a period of two months:

No. and kind of sample.	Average total count per c.c. on Agar at 37° C.	Average number of B. coli.
33 raw water	29,400	3,256 in 1 c.c.
109 treated water	12	1 B. coli in 15 c.c.

86 of 109 treated samples gave 0 B. coli in 50 c.c.
10 of 109 treated samples gave 1 B. coli in 50 c.c.
2 of 109 treated samples gave 2 B. coli in 50 c.c.
2 of 109 treated samples gave 3 B. coli in 50 c.c.
1 of 109 treated samples gave 4 B. coli in 50 c.c.
1 of 109 treated samples gave 5 B. coli in 50 c.c.
*7 of 109 treated samples gave 50 B. coli in 50 c.c.

*The last seven samples showing 50 B. coli in 50 c.c. were taken after the machine had been idle for one month and the raw water controls at the same time had at least 100,000 B. coli per c.c. and a total count of 150,000. If these seven samples are eliminated in figuring the average number of B. coli in the treated water, there would be only one B. coli in 175 c.c. instead of one in 15 c.c. as shown in the table.



Pressure Type Sterilizer, a Companion to the Large Gravity Type, Which Can Be Used for Any Purpose Where a Fairly Large Capacity of Water Is Required.
(Courtesy R. U. V. Co., New York.)

Large Pressure Type Apparatus.

(Capacity, 750 gal. per hour.)

The following table includes a total of 330 samples, taken on twenty-nine different days during a period of two months:

No. and kind of sample.	Average total count per c.c. on Agar at 37° C.	Average number of B. coli
48 raw water	3,900	3,256 in 1 c.c.
282 treated water	7	1 B. coli in 103 c.c.

211 of 282 treated samples gave 0 B. coli in 50 c.c.
31 of 282 treated samples gave 1 B. coli in 50 c.c.
21 of 282 treated samples gave 2 B. coli in 50 c.c.
14 of 282 treated samples gave 3 B. coli in 50 c.c.
3 of 282 treated samples gave 4 B. coli in 50 c.c.
2 of 282 treated samples gave 5 B. coli in 50 c.c.

The bacteriological tests were performed, with slight exception, in accordance with the Standard Methods of Water Analysis of the American Public Health Association. The fermentation of lactose broth and the characteristic appearance on Endo was considered sufficient identification of B. coli.

A total of 391 treated samples were tested. Of these 53, or 13.5 per cent., did not come within U. S. Treasury Department standard of permissible impurity, which requires that not more than one of five 10 c.c. portion of each sample shall show the presence of organisms of the B. coli group. This appears to be a poor showing. However, it cannot be so considered when a comparison is made with the extremely polluted raw water control samples collected at the same time.

In the gravity type of apparatus 86 of 109 treated samples, or 78.8 per cent., showed no organisms of the B. coli group in 50 c.c., while the untreated water contained an average of 3,256 B. coli per cubic centimeter.

In the pressure type 211 of 282 treated samples, or 74.8 per cent., gave no B. coli in 50 c.c., while the untreated water was yielding 2,630 B. coli in 1 cubic centimeter. The great reduction is the more remarkable when one considers the actual time of exposure of the water to the rays is approximately 64 seconds in the large and 30 seconds in the small apparatus, when they are running at their normal rate.

The fact that spore-bearing organisms are somewhat more resistant to those rays than vegetative forms has been shown by von Recklinghausen. In the above outlined tests the lactose broth tubes would frequently show fermentation at the end of 48 hours. In such cases transfers invariably proved negative on Endo for B. coli. The organism that caused this result proved to be a strict anaerobe and was later identified as belonging to the B. Welchi group. It is believed that the appearance of such organisms in water is not of sanitary significance.

Spencer's Conclusions.

The use of ultra violet rays in the purification of drinking water is relatively a recent procedure, and it is believed that the method is capable of further development, with a corresponding increase in efficiency. The method is especially recommended for treating water in circulating systems, in which the water may be exposed many times to the ultra violet rays. Such systems are now used for disinfecting water in swimming pools, hotels, industrial and other institutions. The chief advantage of this method of treatment over chemical methods lies in the fact that objectionable overdosage is impossible. Again, from the standpoint of potability, the water is absolutely unchanged, and hence in this respect is superior even to boiled water. Recently ultra violet rays have been recommended for sterilizing the drinking water on vessels traversing the Great Lakes. The fresh water of the lakes is very clear, and the turbidity that does occasionally occur consists mostly of heavy suspended matter and is easily removed by filtration.

The present forms of apparatus need considerable attention when in operation. Care should be taken to prevent an accumulation of grease or dirt of any kind on the quartz tube. Experience has shown that a very small amount of grease will obstruct the light sufficiently to allow many organisms to pass. Furthermore, the light chamber should be emptied if the machine remains idle for any length of time. This will prevent the growth of algae and other organisms which will obstruct the light when the machine is operated. There is no way to determine when the lamp fails to emit a sufficient amount of ultra violet rays to give a satisfactory water, except by collecting samples and testing the treated water frequently. Theoretically, as long as the lamp remains intact and the vacuum holds, no reduction in the amount of ultra violet emanation occurs. It is stated by the manufacturers that a lamp will wear out before its efficiency noticeably decreases. The proper construction of the lamp is of great importance, and considerable variations have been noted between individual lamps.

In the above tests, since the gravity type gave a higher efficiency than the pressure type, and inasmuch as any lamp operating at a higher voltage is known to emit a larger amount of ultra violet radiation, the use of lamps at a higher voltage, combined with the gravity system, suggests itself as a reasonable line of development.

In regard to cost, the method is not expensive when treating quantities of water of 30,000 gal. or less per 24 hours. For municipal supplies, using several million gallons per day, the expense is considerable, and probably prohibitive.

(To be continued in the November issue.)

An Investigation of the Wet Thiogen Process

In the last several years, the Bureau of Mines, Department of the Interior, has devoted considerable study to various proposed methods for eliminating or recovering sulphur dioxide from smelter smoke. Among these has been included a critical study of the Wet Thiogen Process. The results of the investigations on this process are given in U. S. Bureau of Mines Bulletin 133, "The Wet Thiogen Process for Recovering Sulphur From Sulphur Dioxide in Smelter Gases," by A. E. Wells.

In carrying out the Thiogen Process the gases are first cooled and cleared of all dust and fumes. They are passed through an absorption tower in which the sulphur dioxide is absorbed in water or mother liquor. To the solution of sulphur dioxide is added powdered barium sulphide, when there is precipitated barium sulphite, thiosulphite and sulphur; the precipitate is settled and the mother liquor is returned to the absorption tower. The settled precipitate is then filtered and dried. The elemental sulphur and one-half the sulphur from the thiosulphite is distilled and the sulphur vapors condensed. The residue, consisting of barium sulphite and sulphate, is then reduced to sulphide, which is returned to the operation as a precipitate.

In the investigations of the Bureau, all the operations involved in the process were studied, both on a laboratory scale, and on a scale that may be considered semi-commercial, and the technical possibilities of the process were determined.

The results of these laboratory investigations indicate that the process can be carried out successfully on a commercial scale. No factors were found which would prevent the successful conduct of any of the operations involved.

However, in the reduction of the barium or sulphite it was found that there is a tendency for the formation of barium oxide and carbonate, which will react very slowly in the precipitation operation. Thus these compounds will increase in amount, as the barium is used repeatedly in the cylic operations. However, the proportion of these insoluble barium compounds can be reduced to a low figure by rapid reduction with pure carbon at a high temperature in a furnace externally heated.

In any case, as the soluble barium compounds increase in the cycles the soluble barium sulphide can be leached out and the insoluble compounds allowed to react with strong sulphur dioxide solution, resulting in their conversion to sulphite or sulphate, which can subsequently be reduced to sulphide.

The conclusions from this work were that in some localities the process can be carried out successfully for the recovery of sulphur dioxide in waste smelter gases on a commercial scale and at a cost of about $12 to $13 per ton of sulphur produced.

The Significance of the National Chemical Exposition

(Concluded from page 295.)

"Dyestuff manufacturers, like all others engaged in undertakings which are primarily expected to be profitable, will naturally tend to produce those commodities which are in the most general demand and in the largest use. Whether our newest addition to the industrial accomplishments of the country continues to live and thrive after the war is over, and when, presumably, we shall meet with the desperate competition of interests which are struggling to save for themselves the remnants of trade life which have been left to them, depends on two things—a proper degree of protection against dumping and undervaluations of imports, and an earnest and patriotic co-operation on the part of our manufacturers and color users themselves."

An entire building, constituting one of the units of the large plant of the Federal Dyestuff and Chemical Co., at Kingsport, Tenn., was destroyed by fire on July 5, the loss being estimated at $30,000. A broken electric bulb caused the fire. No serious delay is caused in the general output of the works.

DYE MAKING IS THE MONEYMAKER—I will rent to a corporation or capitalist who can make necessary improvements a suitable factory building and grounds located in eastern Pennsylvania on L. V. R. R. switch; river in rear; ample sewerage; cheap fuel; lot 375 x 200; equipped with two boilers 72 x 16, a 150 H. P. Corliss engine and 80-ton refrigerating compressor all ready to steam up and go ahead. A grand opportunity for a new company to get a factory. Monthly rent $150. Address Box 374, CHEMICAL ENGINEER.

SOME QUALITATIVE TESTS FOR GUM ARABIC AND ITS QUANTITATIVE DETERMINATION

By C. E. Waters and J. B. Tuttle*

The Object of This Paper Is to Bring Together All the More Important Qualitative and Quantitative Methods That Have Been Published, and to Present a New Procedure for the Determination of Gum Arabic. The True Gums Do Not Readily Lend Themselves to Reactions of Definite Qualitative and Quantitative Value, and Therefore the Following Summary of Qualitative Tests Should Be of Interest, As Many of the Quantitative Methods Depend on the Same Reactions.

INTRODUCTION.

The group of polysaccharides includes such diverse substances as the starches, cellulose, the dextrins, the gums, and the plant mucilages. They possess in common the property of being decomposable hydrolytically into one or more sugars, usually pentoses or hexoses. By oxidation, the acids corresponding to these sugars are formed, but the first step toward this reaction appears to be hydrolysis.

The true gums, of which gum arabic is typical, dissolve in cold water, yielding clear solutions which, though viscous and adhesive, can be filtered. The closely related and quite similar mucilages, such as gum tragacanth and cherry-tree gum, simply swell up and form more or less homogeneous suspensions that can not be filtered. Perhaps most of the so-called gums are mixtures of one or more representatives of each of the above two classes.

As might be expected from their chemical nature, the gums do not readily lend themselves to reactions of a definite qualitative or quantitative value. One of us learned how unsatisfactory some of the qualitative tests are when samples of mucilage first came to the Bureau of Standards for examination. This led to an extended study of the literature and of the various qualitative reactions that have been published and finally to a comparatively accurate quantitative method. In the last part of this work the two of us joined forces, hoping to carry on a much more extended investigation than was found later to be possible.

The object of this paper is to bring together all the more important qualitative and quantitative methods that have been published and to present a new procedure for the determination of gum arabic. Since in most cases it is necessary to know only whether gum arabic is present or not, it is believed that the following summary and criticism of the qualitative tests will be of value. Many of the quantitative methods depend on the same reactions.

QUALITATIVE TESTS.

In nearly all cases a 2 per cent. solution of gum arabic was used. Similar solutions of dextrin and of gum ghatti, a substitute for gum arabic, were subjected to the same tests.

1. Ferric Chloride and Alcohol.—A solution of ferric chloride, made up without the addition of hydrochloric acid and filtered to remove a small amount of basic salt, was used. It contained about 25 g of the salt in 100 cc. Neither gum arabic, gum ghatti, nor dextrin gave a precipitate with this reagent.

A mixture of 2½ volumes of 50 per cent. alcohol and the ferric-chloride solution precipitates gum arabic, though often only on long standing.[1] Gum ghatti gives no precipitate, and dextrin a very slight one.

2. Potassium Hydroxide.—According to Liebermann,[2] solutions of gum arabic and of dextrin become amber-yellow when warmed with potassium hydroxide, while the closely related gum senegal gives at most a faint yellow color. Sollman[3] stated that dextrin, when so treated, turns more or less brown, while some sugars and gums, other than arabic, behave similarly. Rideal and Youle[4] came to the conclusion that this test is of no value. Two samples of gum arabic, among a number tested by them, gave a green color. They found that a solution of ghatti turns pink and dextrin a very dark red or almost black. Nevertheless, this test is among those recommended in the latest edition of Lunge.[5]

Our experiments with gums and sugars amply confirmed the statement that this test is of no value.

3. Color Reactions with Phenols.—Reiche[6] found that gum arabic gave a flocculent blue precipitate when boiled with orcinol and concentrated hydrochloric acid. Other carbohydrates, including dextrin, cellulose, sugars, starch, and a number of gums, gave yellow or brown colors.

Ihl[7] was able to distinguish between gum arabic, dextrin, and starch by means of *a*- and *b*-naphthol and phloroglucinol. With resorcinol and pyrogallol, all three carbohydrates gave the same color.

[7] Chem.-Ztg., 9, p. 231; 1885.

In this connection may be mentioned a curious reaction discovered by Clermont and Chautard.[8] A solution of pyrogallol, containing gum arabic, gave a yield of 67 per cent. of the condensation product, purpurogallin (pyrogalloquinone), on standing for two months.

In the hope of obtaining definite color reactions, hydrochloric acid-alcoholic solutions of the following phenols were made up: Phenol, resorcinol, pyrocatechol, guaiacol, hydroquinol, pyrogallol, phloroglucinol, and *a*- and *b*-naphthol. These were heated, in test tubes set in beakers of water on the steam bath, with dextrin and gums arabic, ghatti, and tragacanth. A considerable range of colors resulted: Pale yellow, pale pink, red-brown, brown, pale orange, purple-red, etc., but no reliance could be placed in any of the reactions as a means of identification.

Some interesting results were obtained by heating the same carbohydrates with alcohol and hydrochloric acid, without the addition of a phenol. Dextrin gave no color, gum arabic a pale yellow, and tragacanth a pale pinkish-yellow. A sample of gum ghatti, prepared by powdering together a number of lumps taken at random, gave a pale-yellow solution with perhaps a tinge of pink. The addition of a clear lump of the gum caused no change, while a dark, impure piece produced a dark pink. There may be some connection between these color reactions and the behavior of different lumps of ghatti toward the guaiacol-hydrogen peroxide reagent, which is discussed further on.

4. Basic Lead Acetate.—An aqueous solution of neutral lead acetate precipitates neither dextrin nor gums arabic and ghatti. An alcoholic solution of the salt does, however, slowly precipitate gum arabic.[9]

As might be expected from its employment in clarifying sugar solutions before polarization, basic lead acetate is an excellent precipitant for many gums. The solution may be made basic either by adding ammonia,[10] or by boiling with litharge. The precipitate formed when gum-arabic solution is added is of a peculiar curdy consistency, and of such characteristic appearance that it is hardly necessary to make any confimatory tests.

Allen[11] speaks of this precipitate as a "white jelly." Dextrin solutions are, at most, made slightly cloudy by the reagent, while gum ghatti yields a very small amount of precipitate, most of which remains suspended in the liquid.

The basic acetate solution used by us was made by long-continued boiling of 40 g of crystallized lead acetate, dissolved in 250 cc of water, with an excess of litharge. It was filtered, after which it remained clear for a long time.

Basic lead acetate has been recommended probably more frequently than any other reagent as a qualitative test for gum arabic, as well as for removing this and other gums from wines, liquors, etc., in which other constituents are to be determined.[12]

5. Copper Sulphate and Sodium Hydroxide.—Jettel[13] does not mention the basic lead acetate test, but relies chiefly upon the behavior of dextrin, gum arabic, etc., toward copper sulphate and sodium hydroxide. The test was devised by Liebermann[14] for detecting dextrin and gum senegal in the presence of gum arabic. The precipitate formed in a solution of gum arabic by adding copper sulphate and then an excess of sodium hydroxide, balls together and rises to the top. That from senegal is less in amount and is in finer particles that remain distributed throughout the liquid. On warming, these precipitates dissolve to only a slight extent, and even on boiling there is no reduction to cuprous oxide. A solution of dextrin yields a precipitate that dissolves on warming. The cupric salt contained in the dark-blue liquid is completely reduced by boiling.

To these statements of Liebermann we may add that gum ghatti gives a dark-blue solution which is, at times, slightly turbid, but clears up on warming gently. There is slight reduction on boiling, but this may not be noticed unless a long time is allowed for the cuprous oxide to settle.

In the second part of this paper is described a quantitative method for gum arabic, based on a modification of Liebermann's reagent.

6. Miscellaneous Qualitative Tests.—Many other reagents for gum arabic have been suggested from time to time, but most of them deserve only brief mention.

One of the most interesting of these depends on the presence of an oxidase in gum arabic, and was devised for the detection of this gum when mixed with tragacanth, in which there is no such enzyme.[15] To a suspension of the powdered gum in 30 parts of cold water is added an equal volume of a 1 per cent. aqueous solution of guaiacol, followed by a drop of hydrogen peroxide. If gum arabic is present, the mixture at once turns brown. Dextrin, of course, does not react. Gum ghatti may not react, even after standing for half an hour. With some pieces, however, the color is produced. This recalls the behavior of the gum toward a mixture of alcohol and hydrochloric acid. (See under 3, above.)

Bornträger[16] suggested warming a suspected sample with 50 per cent. hydrofluoric acid. When much bone glue is present, the odor of butyric acid is noticed. Dextrin is detected by its own characteristic odor, while with gum arabic only that of hydrofluoric acid is noticed.

According to Petri,[17] aliphatic aldehydes, certain sugars, and gum arabic give a fuchsin-red color when mixed with alkali and diazobenzenesulphonic acid. The color is gradually developed.

Günsberg[18] used a fresh solution of egg albumen, acidified with acetic or hydrochloric acid, as a reagent for gum arabic. Dextrin yields a dense precipitate which is insoluble in an excess of acid or of dextrin solution. With gum arabic only a little must be added, for the precipitate first thrown out dissolves in even a slight excess. Any albumen that is not precipitated by the gum arabic can be coagulated by heat, although under ordinary circumstances acidified albumen is not coagulable.

Vamvakas[19] found that as little as 5 per cent. of gelatin can be detected in gum-arabic mucilage by means of Nessler's reagent. The mucilage is shaken with one-fourth its volume of the reagent and allowed to stand. If no gelatin is present, the brownish-gray precipitate remains suspended for some days. With an admixture of gelatin the precipitate is dull gray and settles more rapidly. In the presence of tartaric acid even a 30 per cent. solution of gum arabic yields but a slight precipitate with Nessler's reagent.

These reactions call to mind the mixture of mercuric acetate and sodium chloride suggested by Hager.[20] When warmed with glucose there is no change, while gum arabic, dextrin, and cane sugar reduce the mercuric salt with formation of calomel.

In this connection also should be mentioned the reduction of molybdic acid when boiled with a solution of dextrin.[21] A blue solution results, while with gum arabic there is no change.

Analogous to the reaction with copper sulphate and alkali is the formation of a stable blue color when a solution of gum arabic or of dextrin is mixed with cobalt-nitrate solution, followed by dilute sodium hydroxide.[22]

Zsigmondy,[23] using a deep red solution of colloidal gold as a reagent for colloids, studied the color changes produced by glue, gums, albumen, etc.

Other reagents for gum arabic, such as sodium or potassium silicate, borax, or ammonium oxalate,[24] would seem to depend largely upon the natural calcium content of the gum, though some of the reagents are said to produce gelatinization.

In our work solutions of various salts were mixed with 2 per cent. solutions of gum arabic, but in no case was there precipitation or gelatinization. These salts need not be enumerated, except to say that, among others, such promising reagents as basic zinc salts and sodium zincate were found to be useless.

Gum arabic gives no color reaction with iodine solution.

7. Chief Qualitative Tests for Gums and Dextrin.—Most of the tests described above, as well as others not mentioned, were tried. Most of them were unsatisfactory. After the work had progressed far enough to show which tests are reliable we succeeded in obtaining new samples. The five or six lots already on hand were from different dealers and the original sources were not known. The new ones included gum arabic from Khartum and Kordofan, a second supply of gum ghatti, and the closely related gum gedda. It is unnecessary to discuss these in detail since their reactions are included in the table below.

TABLE 1

Chief Qualitative Tests for Gums and Dextrin

Reagent	Gum arabic	Gum ghatti	Gum gedda	Dextrin
Ferric chloride and alcohol.	Precipitate.......	Nearly clear.......	Slight precipitate....	Slightly cloudy.
Basic lead acetate..	Dense precipitate.	Cloudy...........	Less precipitate than arabic.	Slightly cloudy.
Copper sulphate and sodium hydroxide (cold).	Blue precipitate, colorless solution.	Dark-blue solution, often cloudy.	Light-blue precipitate, dark-blue solution.	Dark-blue solution.
As above, but boiled..	Precipitate darker, pale-blue solution.	Slight reduction	Precipitate darker. .	Complete reduction.
Iodine solution.......	(a)	(a)	(a)	Reddish-purple solution.

a No characteristic color reactions.

All samples of gum arabic, from whatever source, behaved alike. Gum gedda, it will be seen, acts much like a mixture of gums arabic and ghatti. Only the tests that are most reliable are included. The gum solutions were prepared by dissolving 1 g. of the solid in 50 cc of hot water and straining through a loose plug of cotton.

QUANTITATIVE METHODS.

Since the chemical nature of the gums is such as to render most of the qualitative tests of at least doubtful value, it is not surprising that there are difficulties involved in their quantitative separation and determination. Some of the methods that have been proposed will be reviewed below, following which our own procedure will be described.

1. Ferric Chloride and Calcium Carbonate.—The first qualitative test mentioned above was the formation of a precipitate when neutral ferric-chloride solution and alcohol are added to a solution of gum arabic. This precipitate is soluble in dilute acid, so that the gum is not completely thrown down unless the acid that is simultaneously set free is neutralized. Roussin[25] found that calcium carbonate is satisfactory for the purpose. The gum solution is mixed with alcohol and ferric chloride, and an excess of the carbonate is then added. The mixture of precipitated gum and ferric hydroxide, which is rather difficult to filter, is washed with alcohol, dissolved in hydrochloric acid, the gum thrown out by strong alcohol, washed with the same reagent, dried, and weighed.

Roussin devised this method for the quantitative separation of gum arabic from dextrin. It is recommended by Allen, and was found by Auguet to give good results in determining the gum in sirups.[26]

[24] Allen: Loc. cit., p. 411.

[25] Loc. cit. See also Allen; loc. cit.

2. Ferric Chloride and Sodium Carbonate.—Another method based upon the reaction with ferric chloride was suggested by Landwehr[27] for the determination of glycogen and, incidentally, of gum arabic. Concentrated ferric-chloride solution is added in slight excess, followed by concentrated sodium carbonate until all of the iron is thrown down. The precipitate is at once filtered off, washed with hot water, dried at 110°-120°, and weighed. It is then ignited and the weight of ash deducted from that of the precipitate.

Determinations were made of the percentages of water held by ferric hydroxide when dried to constant weight at different temperatures. A correction for this water, calculated from the excess of ferric chloride, is applied to the weight of the original precipitate. It is not clear, however, just how this excess is to be determined, nor is the retention of moisture by the precipitated gum taken into account.

3. Lead Acetate.—As already stated, Chauvin[28] suggested the employment of an alcoholic solution of neutral lead acetate for the precipitation of gum, especially from sirups, but found that long standing was necessary. Rocques and Sellier[29] also found that this procedure gives good results.

As far as we are aware, the basic acetate has not been used for the quantitative determination of gum. Various formulas have been ascribed to the precipitate,[30] and it is not unlikely that it may vary in composition.

4. Alcohol.—Chauvin,[31] on account of the slowness of precipitation when lead acetate is used, employed alcohol acidified with hydrochloric acid. The addition of the latter is not necessary, for the gums are all insoluble in strong alcohol. This has often been taken advantage of to remove them from wines, plant extracts, etc.[32]

5. Miscellaneous Methods.—Gum arabic can be hydrolyzed to a mixture of hexoses and pentoses by warming with dilute mineral acid, though not all samples yield these in the same proportions. Hence, quantitative methods based upon the use of Fehling's solution (hexoses), or upon the estimation of furol (pentosans) have failed.[33]

By digesting with moderately strong nitric acid, gum arabic is oxidized to mucic acid, which can be determined with fair accuracy, but samples of gum from different sources yield different percentages of the oxidation product.[34]

Williams,[35] working with quite a number of gums and resins, determined the iodine absorption number and the acidity of gum arabic, as well as the amount of alkali taken up when it is boiled with alcoholic potash. His figures showed that samples of gum differ so widely that methods involving these determinations are of no value.

6. Copper Sulphate and Alkali.—Madsen[36] estimated the gum in licorice juice (succus liquiritiae) by throwing it out with strong alcohol, dissolving in a little water, and then treating with a 10 per cent. solution of copper sulphate, followed by an excess of sodium carbonate. The precipitate is probably identical with that formed by the combined action of copper sulphate and sodium hydroxide. After filtering off the precipitate, it is washed with weaker and weaker soda solution, dissolved in dilute hydrochloric acid, and the gum thrown down by 85 per cent. alcohol. After washing with alcohol it is dried and weighed. The weight, multiplied by 1.21, gives the percentage of gum. This is not said to be identical with gum arabic, but for botanical reasons may well be quite similar to it.

During the course of our tentative experiments, and without knowledge of the work of Madsen, an attempt was made to precipitate gum arabic by means of copper sulphate (5 g of the crystallized salt in 100 cc of water) and sodium carbonate (13.25 g of the anhydrous salt in 100 cc of alcohol of the maximum strength that would give a clear solution). Whether the soda was added before or after the copper solution made no difference in the result. The filtrate was always cloudy, even though the precipitate was so gelatinous that filtration was very slow.

Promising, though still too low, results were obtained with 10 per cent. sodium hydroxide, instead of soda, followed by the addition of enough absolute alcohol to bring the total up to about 60 per cent. strength. The precipitate was washed with alcohol, dried, weighed, and ignited. After deducting the weight of the ash, the percentages of gum found in four determinations varied from 84.6 to 90.1. In each of these four determinations the weight of ash from the copper precipitate was a little greater than that of the gum taken, owing to the fact that there was a considerable excess of copper in the form of hydroxide. Since this increased the time required for drying, besides being otherwise objectionable, some qualitative tests were made with a modified Fehling solution, with the hope that these difficulties would be avoided. Twenty cubic centimeters of copper-sulphate solution and 55 cc of sodium-hydroxide solution, of the strengths stated above, were moved, enough Rochelle salt was added to dissolve the precipitate, and the whole diluted to 100 cc. To a solution of about 0.25 g of gum in 40 cc of water there was added 50 cc of the Fehling solution, but with no apparent change, except at times a slight cloudiness While stirring vigorously, 90 cc of 95 per cent. alcohol was then added, whereupon the familiar blue precipitate formed in fine particles that soon settled. Blanks showed that no cloudiness was produced in the Fehling solution when mixed with water and alcohol in the quantities stated.

[35] Chem. News, 58, p. 221; Z. anal. Chem., 28, p. 732; 1889.

[36] Loc. cit. See footnote 32.

The precipitate was filtered off, washed successively with 50, 75, and 95 per cent alcohol, dried at 110° to 115°, weighed, etc., as before. Two determinations, made exactly as stated, gave the values 95.6 and 94.9 per cent of gum. When the gum was dissolved in 25, instead of 40 cc of water, the percentage found was 97.2. The original dried gum yielded 2.8 per cent of ash, chiefly calcium carbonate, with a little potassium carbonate. No correction was made for this ash in calculating the above percentages. In each of the three determinations just mentioned the weight of the ash from the copper percipitate weighed less than half as much as the gum.

Since the gum-copper precipitate is of a gummy nature, it is not possible to completely remove foreign salts by any amount of washing. Both copper sulphate and sodium sulphate are insoluble in alcohol of the strength used. This is not true of the respective acetates or of Rochelle salt, so that in another series of determinations copper acetate was employed. It is not necessary to go into details further to say that the results were a few per cent below or above 100 with varying dilution of the gum solution and of the Fehling solution, and according to the final percentage of alcohol in the mixture.

Even this reagent was not ideal, for there must always be present the excess of copper salt, as well as the Rochelle salt and the sodium hydroxide and acetate.

7. METHODS FINALLY ADOPTED.—Copper acetate dissolved in ammonia possesses obvious advantages over all the other solutions employed. In order to ascertain the best conditions for precipitation, a few preliminary tests were made. One-quarter gram of gum arabic was dissolved in 50 cc of water, 25 cc of ammoniacal copper-acetate solution (see below) added, and then enough alcohol to give the required percentage of the total volume of the mixture. Thirty per cent of alcohol gave no precipitate. With 40 per cent there was a faint precipitate, so finely divided that it was practically impossible to filter. With 50, 60, and 70 per cent of alcohol, respectively, dense and easily filtered precipitates were formed. The addition of more alcohol to the filtrates from these three caused no further precipitation. These precipitates gave on ignition the following amounts of ash, practically cupric oxide:

TABLE 2

Ash Found With Varying Alcohol Content

Alcohol	50%	60%	70%
Ash	G 0.0412 .0402 .0398	G 0.0436 .0446 .0452	G 0.0544 .0564 .0548
Average	.0404	.0445	.0552

From this it will be seen that in the presence of 50 per cent of alcohol the gum is precipitated quantitatively and carries down with it less occluded matter than when the mixture contains more alcohol.

The following procedure was finally adopted for the determination of gum arabic: Fifty grams of copper acetate was dissolved in water, an excess of ammonia added, and the solution diluted to 1000 cc, using water and alcohol in such proportions that the final solution contained 50 per cent of alcohol. For each determination a 50 cc portion of a gum-arabic solution, representing 0.25 of gum, was pipetted into a 250 cc beaker, an equal volume of alcohol added, and then 25 cc of the copper reagent, with constant stirring. The precipitate was allowed to settle, was filtered on a tared paper, washed with 50 per cent alcohol containing ammonia, then with 75 per cent, and finally with 95 per cent alcohol. It was dried to constant weight at 105°, ignited in a porcelain crucible, and the ash weighed. The amount of ash was deducted from the weight of the original precipitate and the difference called "net gum arabic." The amount of moisture in the gum originally taken from analysis must be allowed for. This is determined by drying in a current of hydrogen at 105°. No allowance is made for the potassium and calcium which form an integral part of the gum. These may be to some extent retained in the precipitate and, therefore, be included in the ash. And error that may be introduced by neglecting this is small and very much less than the error inherent in the method.

In some of the preliminary work the gum-copper precipitate was dried at 95° and then at 105°. The additional loss in weight at the higher temperature was usually about 3 or 4 mg, or 1.5 per cent.

The following table gives the results of a number of determinations on 0.25 g portions of gum. Since this contained 11.5 per cent of moisture, the amount of actual gum was 0.2213g. The precipitates were dried at 105°.

TABLE 3

Results Obtained By the Ammonia-Copper Acetate Method

Series	Total precipitate	Ash	Net gum	Percentage found	Average of series
	G	G	G		
A	0.2570	0.0433	0.2137	96.6	
	.2596	.0428	.2168	98.0	
	.2613	.0470	.2143	96.9	
	.2647	.0469	.2178	98.4	
	.2554	.0413	.2141	96.7	97.3
B	.2970	.0755	.2215	100.1	
	.2840	.0649	.2191	99.0	
	.2837	.0663	.2174	98.3	
	.2887	.0689	.2198	99.3	
	.3012	.0785	.2227	100.7	99.5

	.2927	.0653	.2274	102.8	
	.2982	.0697	.2285	103.3	102.5
General average				99.5	

It is evident from an inspection of the figures that the method as finally modified is capable of yielding as accurate as can be expected. It is realized, however, that much work could yet be done with mixtures of gum arabic with ghatti, dextrin, etc., as well as with mucilages of known composition. A few preliminary determinations, made while Fehling solution was still being experimented with, indicate that dextrin and ghatti tend to be carried down with the gum arabic. At the same time a sample of mucilage was prepared according to the formula in the United States Pharmacopoeia; from this the gum was precipitated by strong alcohol, dried, and analyzed. The net gum found in four determinations was about 91 per cent. This low result may be due to a fault of the method or to partial hydrolysis of the gum. The publication of the results thus far obtained has been so long delayed, and the opportunity to complete the work seems so remote, that it has been decided to present this paper without further postponement.

SUMMARY.

An incorrect report to the effect that a certain sample of mucilage contained no gum arabic led to a study of many of the published tests for this gum, as well as to a search for others than the few that proved to be reliable. It was found that basic lead acetate gives the most characteristic reaction, while mixtures of copper sulphate and sodium hydroxide, and of neutral ferric chloride and alcohol are of value as confirmatory tests.

A summary of the more important methods that have been proposed for the quantitative estimation of gum arabic is next given, followed by a description of the steps that led the authors to the use of alcoholic copper acetate,ammonia solution for this determination.

Concerning the Manufacture of Phthalic Acid and Phthalic Anhydride

The Department of Agriculture announced on June 16, 1917, that the Color Investigation Laboratory of the Bureau of Chemistry of this Department had perfected on a laboratory scale a new process for the manufacture of phthalic acid and phthalic anhydride, and invited cooperation with the manufacturers for the purpose of testing this laboratory process upon a commercial scale. It was also stated in the announcement that the offer of assistance would not be held open by the Department for an indefinite period.

Arrangements have been made with several concerns to test this process on a commercial scale and the Color Investigation Laboratory is not in a position to receive or handle any additional offers of cooperation. The offer made on June 16, 1917, therefore, is withdrawn and no additional offers of cooperation can be considered.

Prof. Judd to Edit A. I. M. E. Bulletin.

As a result of the resignation last June of B. A. Robinson as managing editor of the Bulletin of the American Institute of Mining Engineers, E. K. Judd has been appointed to fill the position. The latter was formerly of the Mining Department of Columbia University.

Primary Volatile Products of the Carbonization of Coal

Technical Paper 140, on the primary volatile products of the carbonization of coal, just issued by the Bureau of Mines, Department of the Interior, should prove of interest to the gas industry, as the authors, Guy B. Taylor and Horace C. Porter, suggest that as a result of their study the utilization of inferior coals in the making of gas may be found practicable.

The authors say that the results suggest the possibility that low temperature carbonization might be utilized in gas manufacture as an enriching process by passing through the low-temperature retorts a relatively large quantity of a thin gas, such as "blue-water gas," sweeping out the light oil vapors that are primarily liberated at these low temperatures.

The report is a continuation of the work described in Bureau of Mines Bulletin 1 on the character of the volatile matter of coal. The experimental methods have been refined and more precise results obtained.

The subject of carbonization is important in all industrial applications of coal, whether it be in gas manufacture or coke making, where it is paramount, or in those processes where coal is burned, such as in boiler furnaces, gas producers, and metallurgical furnaces. The results presented here are more or less of a fundamental character—a study of basic phenomena in carbonization, rather than of the ultimate results of these phenomena as a whole.

The authors, in their general conclusions, say: "A high-grade bituminous coal of the gas-making type decomposes by heat primarily into paraffin hydrocarbons and a completely altered nonvolatile residue, with small quantities of water, CO_2, and CO. The three latter products are the first produced, although in small quantity; from some other types of bituminous coal they are produced in greater relative quantities than from the gas-coal type. Complex and varied secondary reactions induced by superheating the hydrocarbons, water vapor, and CO_2 are of great importance in industrial high-temperature carbonization.

"The products of low-temperature carbonization from coal of the Pittsburgh type on an industrial scale at about 800° to 900° F. (427° to 482° C.) will consist of a rich gas amounting to 0.6 to 0.7 cubic foot per pound of coal, and a large yield of oil, or tar, comprising 10 to 12 per cent. of the coal. This tar consists chiefly of paraffin hydrocarbons, is very low or possibly entirely devoid of benzene and naphthalene derivatives and practically devoid of free carbon. The gas will contain 6 to 7 per cent. of unsaturated hydrocarbons and 20 to 25 per cent. of ethane and its higher homologues, and consequently will have a high calorific and illuminating value. The tar may be either redistilled or subjected to cracking processes so as to produce light oils—gasoline substitutes—whose yield will be greater than, and probably at least double, that obtained by high-temperature carbonization.

EDITORIALS

Death of Dr. Eugene F. Roeber

In the death on October 17, 1917, of Dr. Eugene Franz Roeber, the chemical journalism of New York City loses one of its most forceful and valued members.

Dr. Roeber was born in Torgau, Germany, October 7, 1867, and he had barely completed a half century at the time of his passing away.

His scientific studies were pursued at the Universities of Jena, Halle and Berlin. In 1892 he received the degree of Ph.D. at Berlin. He belonged to a family bitterly opposed to the oppressive restrictions of Prussianism, and soon after the completion of his studies sought the freer atmosphere of America.

Coming to the United States in 1894 he led for a few years an uneventful life in New York City, connected for some time with the Steiger book importing company. In 1899 he became the assistant of Dr. Carl Hering in Philadelphia, and soon made himself felt as a prominent factor in electrochemical circles. In connection with Dr. Hering and Mr. C. T. Reed he was instrumental in founding the American Electrochemical Society. The rapid growth and marked success of this organization has been largely due to his untiring efforts. It found an appreciative recognition in 1914, when he occupied the presidency and when its members presented him with a silver loving cup as evidence of their high personal regard for the many attractive traits in Dr. Roeber's character

It was during his sojourn in Philadelphia that Dr. Roeber found his real vocation Electrochemistry was growing so rapidly in importance that the need of an organ became evident. In 1902 *Electrochemical Industry* was started and Dr. Roeber was made its editor. The year following the office was removed from Philadelphia to New York. The journal rapidly gained in importance and influence. Its title in 1905 was changed to *Electrochemical and Metallurgical Industry*. In 1906 it absorbed the *Iron and Steel Magazine*. Finally, in 1910, it broadened its field, assuming the present title of *Metallurgical and Chemical Engineering*.

Throughout these fifteen years of journalistic activity he displayed the widest interest in general science and engineering, and a remarkable catholicity of knowledge. His writings showed a spirit of generous tolerance and a constant longing to be helpful and stimulating to others.

His circle of professional friends grew to be very large and his work was highly appreciated beyond the Atlantic. It bore the imprint of great ability and sterling character, coupled with an indefatigable love of work. It was, in fact, this willingness to undertake a variety of difficult tasks, and his high standard of conscientiousness in their execution, which led to the undermining of his vitality, when he seemed to be in his prime. For nearly a year he struggled with increasing weakness, until in June of this year he was forced to lay down the pen.

There seems to be no doubt but that the events in his native land contributed to the results of overwork. A thorough lover of his adopted country, a convinced believer in her mission in behalf of democratic ideals, like so many others among our loyal citizens born in Germany, he was forced to witness in silence the perpetration of crime after crime in his Fatherland, creating the deep, wide chasm which for decades hence will separate from the rest of the world the Germanic race.

It was a marvel to his friends that Dr. Roeber so rapidly attained the ability to express himself in English with such felicity and such force. His style was easy and attractive, thoroughly idiomatic, recalling the admirable editorial work in distinctly political fields of Carl Schurz, who fled from his native land at about the same age.

Dr. Roeber was actively identified with all organized effort to further American chemistry. In addition to the American Electrochemical Society he was an active member of the American Institute of Mining Engineers, the American Institute of Electrical Engineers, the American Institute of Chemical Engineers, the Society of Chemical Industry, and the American Chemical Society and the Chemists' Club. In the latter he belonged to the Committee on Library and Art.

Dr. Roeber was married May 6, 1900, to Miss Clara H. Feir of New York. He is survived by his widow and three sons.

Apart from his professional work, Dr. Roeber was a notable figure in the social scientific life of New York. Bubbling over with enthusiasm, genial and sympathetic he attracted friends and admirers with singular ease. The number of those who will deeply miss him is exceedingly large.

Exemption of Chemists from Military Duty

In the inevitable haste required to organize the selection of the great army of American youth, now in training, and soon to be found on the firing line in Europe, we have not adequately profited from the experience of England and France. There, also, in 1914 was seen the same hurry to bring together with the least possible delay, every man capable or willing to carry a rifle. Ere long it was recognized that the engineer, the electrician, the chemist, and others of high scientific training, could render far greater service to the cause of national defense at home than in the trenches.

Then came the period, unfortunately after many had fallen, when they were gradually summoned back to deal with a multiplicity of problems of prime importance. Chemists in particular were required to handle all the questions involved in assuring an enormous output of explosives of every form, in combating the use of gases in warfare, in establishing the manufacture of drugs and general chemicals formerly secured from the enemy and in producing rapidly a host of articles essential for modern warfare.

On this side of the ocean there has been a tardy issue of regulations, exempting medical students and hospital internes. There has been, however, no action tending to free chemists from the action of the draft and save to the most vital industries of the land the men whose knowledge and training, now or later, will be of incalculable value for national defense or for preserving the integrity of our industrial fabric.

Dr. Wm. H. Nichols, chairman of the Committee on Chemicals of the National Research Council, has given this matter much thought in connection with his colleagues. At the recent meeting in Boston of the American Chemical Society he made the following forcible statement in depicting the activities of his committee:

"One of our most serious difficulties arises from the unwillingness of the military authorities to recognize the wisdom of exempting chemists as a class from the draft. Almost from the beginning of our work we took up this question from various angles, realizing as we do the vital importance of keeping chemists at work in their profession, not only at the present time, but more particularly for the future. Our civil, mechanical, electrical and other engineers can be made good use of at the front, and not only contribute greatly to the success of our forces, but by the valuable experience obtained in their profession can improve themselves for future service at home. This is not true of chemists, with an exception here and there. Once in the army and at the front, if he be only recently out of college, he is lost to chemistry forever. They are not slackers and are just as anxious as any other red-blooded young men to get into the fray, and therefore I have believed it wise not only to have them exempted from the draft but declined in case they should enlist. Already serious trouble has come to many of our chemical plants and plants employing chemists, as a result of the draft, and unless wise provision be soon made we can foresee a condition which it will cost months to rectify. Why should we not take advantage of the experience of our English friends who have passed through this same situation, and learned that there is a large class of men who can do more valuable work behind the lines than they can in the trenches?"

A Threatened Shortage in Sulfuric Acid

The manufacturers of artificial dyestuffs and of other synthetic coal-tar compounds are forced to face a new dilemma in addition to several others resultant largely from the abnormal demand for munitions.

This latest cause for anxiety is the threatened scarcity of sulfuric acid. It is due in part to the immense increase in the demand for acid, as a result of the rapid expansion of American chemical industry and of foreign requirements, chiefly, however, to the lack of raw material.

In the past large amounts of cheap Spanish pyrites, much of which had been treated and leached for its copper content, have been brought across the Atlantic at exceedingly low rates, practically as bal- submarine menace, these shipments have almost last. Under existing conditions, following upon the ceased.

It seems difficult to increase in any very material degree the current output of Louisiana sulfur or that of pyrites from American mines. Elaborate construction would be necessary in order to utilize upon a larger scale, than is the case at present, the roaster gases of our western smelters. They are also far removed from the region of intensive consumption, and there is the heavy handicap of the freight charges on the transportation of acids.

During the year ahead the consumption is expected to reach about 8,000,000 tons, and facilities for producing less than two-thirds of this amount are in sight. Quotations for sulfuric acid have reflected for months past the threatened shortage.

In the manufacture of coal-tar colors no other chemical is required in such amounts. Every operation of nitration requires an equivalent amount of sulfuric acid to act as a dehydrating agent. In the preparation of the many sulfonic acids, called for in rapidly increasing quantity, two molecules of H_2SO_4 are needed for every substituted HSO_3 group. It is evident that any serious lack of the acid will affect very noticeably the expansion of our color industry in regard to both cost of production and available supply.

Chemists are already studying how to economize in the use of sulfuric acid, as well as how to stimulate the production. There is a growing use of the free acid present in niter cake, or acid sodium sulfate, hitherto so largely disregarded. Much of the spent acid, resulting from nitration and ordinarily allowed to go to waste, can be recovered by employing proper means for concentration. This is being done on an increasing scale in England. Means have also been devised for recovering SO_2 from the flue gases of furnaces in which zinc blende is smelted. This recovery was highly perfected in German smelting works before the war and it could be profitably employed in this country. It would release a notable amount of sulfur now used in making sulfites for the paper industry and similar branches.

While we can trust to American enterprise and ingenuity to prevent any very acute shortage in the supply of the acid, it is probable that until the end of the war all consumers of sulfuric acid must count upon an exceptionally high price for their supplies.

Prospective German Competition in the Color Trade

Our American manufacturers of synthetic colors while losing no time in expanding the variety of their products, and co-ordinating all parts of their industry, are forced to consider at every point the possibility, or rather certainty, of the keenest imaginable competition after the war on the part of the great German firms, who have hitherto controlled the situation. Just how far the fairly generous protection for coal-tar products, contained in the Congressional enactment of September 8, 1916, will suffice, in many individual cases cannot be accurately estimated until the American maker is brought actually face to face with foreign competition. The effectiveness of the provisions to prevent underselling and unfair competition will be known only after the machinery is in genuine operation.

It is felt that in most cases the American producers of coal-tar colors and other synthetic preparations can confidently await the ordeal. The mechanism of manufacture will be practically standardized, and the all-important trade relations with the consuming public will have been established.

In some cases, however, the margin of safety may be quite limited. This is to be expected, more especially in the categories of colors in limited demand and of those the manufacture of which may be introduced very shortly before the return of normal exchanges. Our chemists will tend to measure more and more carefully the probabilities of an early peace as they undertake new problems and consider the factors of success.

The uncertainties faced by American manufacturers of dyes are, however, much less serious than those to which British colleagues are exposed. Thus far there has been no attempt to enact at London the protective legislation regarded as absolutely necessary to ensure the healthful growth of a domestic color industry, at least during the initial years. The great complexity of the problem is fully recognized and is attracting general attention. Some of the many factors involved were considered recently in an article in the Manchester *Guardian*, from which the following extract may be of interest to American manufacturers:

"The supplying of all the varied needs in dyestuffs of every trade is a bigger affair than most people conceive. Can we undertake to supply, for example, the hatting trade with just the blacks they require for their fur felts, or the calico printers with a complete range of fast and easily dischargable colors for lining styles, or the worsted cloth manufacturers with a black which will withstand their 'potting' process? Possibly these, which are taken at random, and yet not others, for the difficulty is not one of bulk but of variety. In certain directions we are still held back by lack of raw material, and here we may expect immediate improvement with peace. Then also we may look for a rapid ripening to production of much patient research. We may even expect to be well supplied with azo colors for both wool and cotton; but here, and more inevitably in other directions, there will be gaps which will be at least awkwardly felt by almost every branch of the coloring trades.

"Undoubtedly, however, the English dye manufacturers will have as an asset the prevailing anti-German prejudice; nor is it likely that prices will immediately drop to unremunerative levels. There will be no 'dumping,' for, as the German trade journals testify, there is no accumulation to dump and no incentive to sell at cost when high prices tempt German production into every other civilized country. What may be anticipated, however, is a very considerable modification of the former German methods of propaganda.

"It will be worth our while to consider those insidious propagandist methods of the German colormakers from the point of view of a British dyer of good standing. In pre-war times he was assured by experience of a conscientious regularity in shade and strength of consecutive deliveries, and supplied with a great number and variety of tasteful pattern cards, illustrating complete ranges of dyes suitable for his own branch of trade or new dyes which might be of interest to him, with full details of fastness and methods of application. Some of these were really valuable books of reference, and were said to have cost half-a-guinea a copy to produce. The pattern card departments of the large firms were very completely equipped."

Prospective Competition of Japan in the Manufacture of Dyestuffs

With each passing month the ability of Japan to build up a varied chemical industry is becoming more and more evident. The same conditions favor its growth which are now stimulating so marvelously the expansion of the American chemical industry. There is the same insistent domestic demand, the same flood of inquiries from various lands, all seeking to secure supplies which hitherto have come in abundance from Europe, and more particularly from Germany.

Japanese chemists have utilized the situation quite as promptly as has been the case in this country. One branch after another has been organized and brought into effective operation. In some instances, notably in regard to the prussiates and potassium chlorate, the output has already out-distanced the local needs and the product is seeking foreign markets.

The question naturally arises, to what extent may this affect our growing American industry, when normal conditions are restored, and especially our coal-tar chemical industry.

At present our domestic consumption eagerly absorbs all of the prussiates and potassium compounds which Japan can send us, and pays good, round rates for the same. There is a feeling in the Island Empire that these conditions may continue indefinitely, and that numerous other chemicals may be included in the list. This confident expectation is based largely upon the existing cheapness of manual labor, the daily wage of Japanese operatives averaging about 50 cents in gold.

It is doubtful, however, whether the Japanese chemical industry, with this unquestioned advantage, can hold its own in competition with highly organized European and American industries.

In most branches of technical chemistry, the labor cost is a minor item in the budget of a factory. The prices of raw materials, of fuel, of electric power, of transportation to markets, are controlling factors. Most of these elements of cost are quite as high for the Japanese producer as for his American competitor. He faces, in addition, an American tariff.

The natural resources of Japan are not of a character to form the foundation of a well-balanced chemical industry. Most raw materials must be imported. It is true that China, with her inexhaustible coal deposits and many other mineral and organic products, is close at hand, and at the same time, offers a market for a vast amount of chemicals and dyes.

Japanese chemists have shown great ingenuity and perseverance in securing notable quantities of potash and iodine, as well as of other substances from the kelp of the Pacific, but apart from this feature they are heavily handicapped. The metallurgical industry is but slightly developed and the coking plants are few. Any material expansion of the recently started dyestuff industry would involve dependence upon this country or other sources for the raw material.

Under these circumstances it is extremely improbable that Japan may count as a serious factor in the future of our dyestuff industry. Her chemists are still dealing with elementary problems, and are not yet as far advanced in coal-tar chemistry as were scores of American chemists when the world war broke out. They display commendable pluck and energy, and undoubtedly will create a domestic industry fairly adequate for their country's needs. When the time comes for expansion, it would seem as if China will be the natural field for their operations. The market is at their doors and presumably they will depend to a considerable extent on Chinese coal. China already consumes large quantities of artificial colors, and is, in fact, the chief consumer of synthetic indigo. With the rapid opening of the republic to modern industrial ideas and practices, its vast population will constitute, ere long, a market of enormous consumptive possibilties.

As normal trade relations return we may, therefore, witness rather an opening in Japan for much of the excess of our chemical output, than any pronounced movement in the opposite direction.

At the same time we may confidently expect that the Japanese color industry, aided by its governmental subsidy, will soon reach the point where it will effectually meet the nation's demands. There will be but a limited opportunty for dyes of American or even German make, and Japanese products may meet us competitively in the adjacent markets of the Far Orient.

Dr. Johnson Commissioned.

Dr. James J. Johnson, expert on high explosives, formerly chief chemist for the Maas & Waldstein Company, has received a commission as captain in the Ordnance Department, U. S. A. He will serve in the gun division.

Phio Color Works.

Dyestuffs and allied products will be manufactured by the Phio Color Works, New York, which was recently incorporated in that state with a capital of $5,000 by L. W. Alexander, F. C. Simons and M. Winters, 595 Eastern Parkway, Brooklyn.

American Coal-Tar Products Industry Production To Be Ascertained by the United States Tariff Commission.

The United States Tariff Commission is planning to ascertain the production within the United States during 1917 of all substances treated in Title V of the Special Tariff Act of September 8, 1916. The substances there enumerated may be classed under the general Coal-Tar Products, and are divided into three groups.

Group I includes "all products that are found naturally in coal-tar, whether produced or obtained from coal-tar or other source" except phenol. These substances are admitted free of duty.

Group II includes the so-called Intermediates and are made dutiable at 15 per cent. plus 2½c. per pound.

Group III includes "all colors, dyes, or stains, whether soluble or not in water, color acids, color bases, color lakes, photographic chemicals, medicinals, flavors, synthetic phenolic resins or explosives, not otherwise specially provided for in this title, when obtained, derived or manufactured, in whole or in part from any of the products provided for in groups I and II." These articles are dutiable at 30% plus 5 cents per pound with certain exceptions which are dutiable at 30%.

Under the law the duties are made dependent on the growth of the industry within the United States. It is therefore the intention of the Commission to follow this growth from year to year in order to report the facts to Congress.

The Tariff Commission is planning to send to each manufacturer a questionnaire calling for information in regard to his production during 1917 of each separate commodity, as well as for certain other data. This information will be published in such a form that the operations of individual firms will not be disclosed. A preliminary questionnaire has recently been sent out, designed to aid in perfecting the mailing list. Any individual or firm engaged in the manufacture of any of these articles which did not receive a copy of the preliminary questionnaire is requested to write to the United States Tariff Commission, Washington, D. C., to insure being placed on the mailing list.

COAL-TAR CRUDES

Crude Benzols

One great difficulty in solving the problem of the production of benzol and toluol by carbonization of coal has been the lack of a rapid, simple and reliable test for the benzol content of the gas and of the crude benzol produced. P. E. Spielmann and G. C. Petrie, in the July 31 issue of the Journal of the Society of Chemical Industry, give some interesting figures obtained from nine coke-oven benzols analyzed by recent methods compared with simpler operations that are suggested by the authors. A preliminary distillation up to 170° C. was made, determining the per cent. of distillate, its specific gravity, loss after treatment with NaOH and H_2SO_4, and after subsequent steam distillation. A fractional distillation was also made, the per cent of distillate up to 90°, and from 90° to 140°, composition of these fractions expressed as per cent benzene, toluene, xylene, paraffin, carbon bisulfide and residue being determined. The volume per cent of distillate under 120° by the retort and the distillation tests and the specific gravity of all fractions, were found.

When curves are plotted showing percentage of distillates at the various temperatures up to 170° for the preliminary distillation, the horizontal distances between 5% mark and the point where the curve cuts the 92.5° C. line give a close measure of the percentage of the benzene present while the quantity of toluene is proportional to the number of millimeters of maximum deviation of the experimental curve from the smoothed curve shown dotted on the graph. The percentage of liquid obtained by distillation up to 120° is very closely approximate to that of the washed liquid boiling up to 140°. By means of a plot or graph it is shown that the specific gravity of the portion fractionated up to 170° correspond fairly well with the quantity to 140°, and the per cent loss on acid washing plotted against the quantity of the three components benzene, toluene and xylene found in the distillate up to 170°, seems to show that the two main constituents occur in inverse connection with one another and that combined with the xylene, the total aromatic substances in the fraction up to 170° show a remarkably constant inverse relationship to the loss on acid washing.

A preliminary distillation therefore up to 170° C., noting the volume of distillate at 120° and at 170°, the specific gravities of the fractions, and the per cent loss on acid washing, will, when plotted as described, furnish valuable information.

The Tar Industry of Great Britain

In the report for 1916 of the British Alkali Inspector there are interesting surveys of the extent and character of the tar industry, which has expanded rapidly of late as a result of the pressing demand for raw material in the manufacture of high explosives. We quote the following:

"The number of tar works registered was 316, as compared with 248 in 1915, a difference of 68. This large increase was almost entirely due to the rapid extension of the use of tar-dehydrating plants in gasworks. Those plants designed to effect continuous distillation were very widely adopted. In some cases, however, simple plants were erected at a much more moderate cost which gave quite satisfactory results. In several districts plants designed upon the continuous system were not provided with sufficient condensing power. This is a serious fault, as not only did it lead to an escape of objectionable vapors, but to a loss to the country of an unknown quantity of benzol and toluol at a time when every effort should have been made to conserve these to the utmost for munition purposes.

"Whilst it may be to the interest of individual gasworks proprietors to provide small tar-dehydrating plants, it is of doubtful advantage to the community to have numerous small units for treating tar put into operation without specially skilled supervision to ensure such plants being worked to their full advantage. Plants of faulty design, apart from inefficient condensation, have been put into operation which must have affected prejudicially the quantity of products obtained. In the works of experienced tar distillers or in factories worked under skilled supervision through co-operation of a number of conveniently situated gasworks, it is unlikely that such plants would have been put into operation without modification. Combined effort with high efficiency through skilled control will always beat individual effort with variable efficiency and often devoid of specialized control.

"The means in use for preventing the escape of noxious gases underwent no change. Apart from the temporary undue escape of vapors of volatile hydrocarbons, due to insufficient condensing plant, these works were conducted satisfactorily as regards the requirements of the Act.

"The quantity of tar operated on in the United Kingdom was as follows:

Tar distilled in—	Long Tons
Gas works	1,420,867
Other works	138,552
Pitch produced in—	
Gas works	715.051
Other works	83,690"

Distillation of Tar Oils.

An Australian inventor, W. R. Grimwade, of Toorak, near Melbourne (Br. Pat. 108,004, of 1916), has devised a method to obviate the objectionable odor clinging to phenol, the cresols and other tar oils, obtained by the distillation of coal tar. He claims that it is due to the presence of oxygen in the still, during the operation of distillation, and remedies the difficulty by maintaining in the still an atmosphere of inert gas, such as carbon dioxide, nitrogen, or simply flue gases. The non-oxidizing gas is introduced through a pipe terminating slightly above the floor of the still.

Control of Coal Tar in Great Britain.

After Oct. 1 all transactions in coal tar throughout the United Kingdom can take place only under license from the Ministry of Munitions. Every effort is being made to assure an adequate supply of benzene, and especially of toluene, for use in the manufacture of high explosives.

COAL-TAR INTERMEDIATES

The Manufacture of Anthraquinone

There is a growing feeling that our American color industry should promptly enter upon the manufacture of alizarin and the other important dyes derived from anthraquinone. In this connection we reproduce from "La Revue Produits Chimiques" a full account of the current process, now employed in Europe, for transforming the hydrocarbon anthracene into anthraquinone:

By oxidation anthracene yields anthraquinone according to the equation:

$$C_{14}H_{10}+3O=C_{14}H_8O_2+H_2O.$$

As this oxidation is effected industrially by means of chromic acid it may be formulated as follows:

$$C_{14}H_{10}+Na_2Cr_2O_7+4H_2SO_4= C_{14}H_8O_2+Cr_2(SO_4)_3+Na_2SO_4+5H_2O.$$

It is performed in large wooden vats, lined with lead, holding 10 to 12 cubic metres. The vats are heated with direct steam and furnished with agitators. A vat is charged with sumblimed anthracene, still in form of paste. The charge is 150 kilos of anthracene to 3,000 to 4,000 litres of water. The temperature is raised to 75° C., and, with constant stirring, 2,000 litres of a chromic solution, containing 100 grammes of chromic acid and 250 to 300 grammes of sulfuric acid at 66° Bé. per litre, are added gradually. The 2,000 litres, therefore, contain 300 kilos of bichromate of soda and 600 kilos of sulfuric acid. During the operation the temperature gradually reaches 95° C.

The oxidation is carried on for twelve to sixteen hours, and does not present any particular difficulties. The chromic acid must not be added too quickly, and the solution must not be too concentrated. Otherwise a persistent and troublesome foam is produced. The reaction is controlled, from time to time, by testing samples. A sample is filtered, washed, then sublimed over the naked flame in a small test-tube, and, with a little practice, it is easy to see if the anthraquinone is pure or whether, on the other hand, there is still anthracene present.

The anthraquinone sublimes in fine needles, whereas anthracene forms silvery scales, easily recognizable.

It will be seen by the proportions given that the bichromate is employed in excess; 200 kilos of bichromate, theoretically, should be able to oxidise 175 kilos of 95 per cent anthracene.

When the oxidation is terminated the contents of the vat are forced by a pump through a filter press, in which the anthraquinone is thoroughly washed. If the anthracene used is sufficiently pure, the yield is about 110 per cent of anthraquinone.

The anthraquinone thus obtained is sublimed by steam is an apparatus similar to that used for anthracene. On the sublimation the weight is reduced; the theoretical 117 per cent falls to about 80 to 85 per cent.

Formerly, when non-purified anthracene was oxidised, the anthraquinone obtained was very impure, and had to be treated with two or three times its weight of sulfuric acid (66° Bé.) at 100° C., until a sample poured into water gave an almost white precipitate. By this treatment the impurities became soluble in water, whereas the anthraquinone, being insoluble, could be separated out. Since purified anthracenes have been obtainable, this operation has disappeared, sublimation alone being generally sufficient to bring the anthraquinone to a sufficiently pure state for ordinary purposes. The sulfuric acid treatment is still resorted to, however, in the rare cases when an extremely pure anthraquinone is required.

Anthraquinone forms yellow crystals. In a finely divided state it is almost white. The fusing point is 284.6° C., the boiling point 382° C. It sublimes very easily. It is completely insoluble in water, slightly soluble in alcohol, ether, and benzene in the cold, rather more soluble with heat in benzene and in glacial acetic acid.

It is not a commercial product. Apart from a limited use as catalyser in certain sulfoxylate discharges, it is employed solely in the color works.

It is interesting to note that it may be synthesized without using anthracene as the point of departure. Phthalic acid is condensed with benzene in the presence of chloride of aluminum. This gives ortho-benzoyl-benzoic acid. By anhydrisation with hot concentrated sulfuric acid this gives anthraquinone. The reaction is so simple that its industrial application has been considered. As a matter of fact, although it has not been used for anthraquinone itself, it is employed in the synthesis of different derivatives of anthraquinone.

A very important factor in the economy of anthraquinone manufacture is the regeneration of the chrome, which, after oxidation, is in the state of chromic sulfate. This can be crystallised and recovered in the form of chrome alum, after the addition of the necessary quantity of sulfate of potash or of sulfate of ammonia, as the ammonia alum crystallises as well as the potash salt.

The high price of chrome alum, which is very largely used at the tanneries, makes the recovery of importance. An annual production of 300 tons of anthraquinone nearly corresponds with the French consumption, and in the manufacture 1,500 tons of chrome alum are obtained.

Another way is to precipitate the chromic sulfate with soda, which gives chromium hydroxide used in the preparation of chromium acetate, chromium fluoride, and other salts used in the textile industries. In the German works the chromic acid is recovered by electrolysis, which is by far the most economical way where the electric current is cheap.

Uses.

Except for certain special purposes, anthraquinone serves almost solely as the raw material for the anthraquinone colors, of which alizarin is the most important. By sulfonation, nitration, chlorination, and other processes nitro-anthraquinone, sulfo-anthraquinone, chloro-anthraquinone, amido-anthraquinone, etc., are prepared, and these serve as intermediaies for the manufacture af a large variety of valued dyes.

A New Class of Anthraquinone Intermediates

Paul Nawiasky, of Ludwigshafen-on-the-Rhine, Germany, assignor to the Badische Anilin & Soda Fabrik. (Amer. Pat. 1,238,932, of Sept. 4, 1917), has invented a new class of anthraquinone derivatives, which promise to be of value as intermediates in the manufacture of colors. The method of production consists in reacting on an anthraquinone-beta-sulfonic acid body with an amino compound of the benzene or naphthalene series, in the presence of strong alkali, until the sulfonic acid residue is split off.

The new compounds of the anthracene series are anthraquinone-beta-arylides of the formula:

A—NH—R.

A represents an anthraquinone residue, free from SO_3 groups. R represents an aromatic residue containing less than fourteen carbon atoms. The operation is preferably carried out in the presence of air or of a solid oxidizing agent such as potassium chlorate.

These anthraquinone-beta-arylides are insoluble in water, dilute acids and alkalis, soluble in organic solvents and in concentrated sulfuric acid. The solutions in the latter turn, when heated, into blue or bluish violet. When treated with sulfonating agents, they yield wool dyes with good properties.

The following example illustrates the process of manufacture:

Heat one thousand parts of aniline to the boiling point. After any water that may have been dissolved therein has been distilled off, add thirty parts of powdered caustic soda and one hundred parts of anthraquinone-2-sulfo acid sodium salt. Keep the mixture boiling for about five hours, preferably while well stirring, and passing an ample current of air through the mass. After cooling, remove the excess of aniline by dissolving it in dilute hydrochloric acid and extract the insoluble residue with dilute alcohol. Dry it and recrystallize, for instance, from chlorobenzene. The red crystalline needles, thus obtained, are 2-phenyl-amino-anthraquinone. They melt at 234° to 236° C.

Other salts, or derivatives, of anthraquinone-2-sulfo acid, or the free acid, can be used instead of sodium salt, for instance, the aniline salt, or the anilide. Instead of aniline other amino compounds of the benzene or naphthalene series can be employed. Para-toluidine yields 2-para-tolyl-amino-anthraquinone in the form of crystals melting at 234° to 235° C. Para-chloro-aniline yields 2.4′-chloro-phenyl-amino-anthraquinone, crystals melting at 302° to 303° C. Aniline and 2-chloro-anthraquinone-7-sulfo acid sodium salt yield orange colored needles of the corresponding anilide which melt at 276° to 277° C.

Picric Acid Works in Great Britain

The report, for 1916, of the official charged with the inspection of the British factories for the manufacture of picric acid shows that much is being done to restrict the damage due to the escape of nitric fumes, but that much remains yet to be done. The following extracts are of interest:

This class of works increased in number, all the new factories being of important productive capacity. Large extensions also were carried out in factories already in operation.

The treatment of waste fumes in this class of works still leaves much to be desired. The volume of these has grown with the increased scale of operations. Advance has been made in some of the factories by collection and condensation of the objectionable discharge, but in many cases much yet requires to be done in this respect.

Various influences have adversely affected progress in dealing with the fumes evolved in these works:—difficulty in obtaining the necessary earthenware appliances—partly through limited production, and partly through the large demands for material of the kind required to equip new productive plant for picric acid manufacture. An explosion, which led to the destruction of an extensive plant, not only made increased calls for material to make good the destruction caused, but led to the most regrettable loss of the life of one who was taking an active part in bringing into operation an efficient fume-recovery system.

Improved methods for reducing working losses of picric acid and for the recovery of the waste acid remaining from the process—a question of prime national importance—took up part of the attention of the management, as well as much of the labor available at the works.

In those cases where definite progress has led to practical results much improvement has been effected. Not only were the noxious fumes effectually dealt with, but the conditions of manufacture were better under control, resulting in greater yield of high-quality product and decreased consumption of material, whilst the capacity of production of plant was increased, when compared with operations under the previous conditions.

Complaints were made, and made with justification, against some of these works in which it was difficult to effect rapid improvement under the unusual circumstances, but an early advance in fume treatment is now looked for.

Serious Explosion in Munitions Plant

The most serious accident that has happened in any American chemical plant since the making of munitions was started, occurred at the works of the Curtis & Harvey Company, at Rigaud, Que., on August 18. The marvel was that with two hundred and fifty men working in and around the buildings and a total of four or five thousand hands employed by the company, so few fatalities resulted from the fifty explosions which followed the first. While several were injured, only one man, so far as reported, was killed, and this was an expert who had been brought out from England as foreman of the works. The loss in material, buildings and plant is estimated at $2,000,000. The village of Dragon, some distance from the works and containing about forty houses, was practically wiped out by the explosions and the fires which followed, and tons of metal were hurled around the country for nearly a mile. For example, a piece of boiler plate weighing over a ton was found half a mile away, and it is remarkable that none of these fragments killed any of the inhabitants. Two farm houses more than a mile away were blown down. Through the heroism of a telephone operator, a rescue train was called from Montreal and was soon on hand.

Though the cause of the accident will probably remain obscure it is fairly certain that it was due to some omission or carelessness in the operation of the plant. At the coroner's inquest, George Dufresne, the foreman in the nitrating department, said that he had been working in the plant since December and had had no previous experience in the making of trinitrotoluol. At 9 A. M. he had noticed that No. 6 nitrator was acting strangely. He explained that there were six large nitrators in the plant, 12 feet deep by 9 feet in diameter, which were used to agitate the toluol and the nitre and sulfuric acid. At the time of the accident, two were empty and four were filled. The charge in No. 6 had been finished and the contents were ready to be emptied through a pipe into another tub, where the acid was separated. "I saw white smoke coming out through the cover," said Dufresne. "This was followed by fire, and I knew then that everything was going. There were nine men in the plant, and I told them to run for their lives. I sent two men to warn the others. The explosion soon followed." Witness said that there had never seemed to be any defects in the vats other than what could be immediately corrected. There was no possibility of the explosion being caused by outside interference, as no outsider was allowed to look into the nitrator. Timothy Curtis, vice-president and general manager, said that in the ordinary course of events the material did not offer any danger. There was danger in case the acid got too hot, but the principal danger was from the acid fumes. He thought the fire was caused by spontaneous combustion through the decomposition of the chemicals.

The reconstruction of these works depends on contracts to be concluded with the United States government.—The Canadian Chemical Journal.

Catalytic Synthesis of Aromatic Substitution Products

Frederick G. Keyes, of East Orange, N. J., assignor to the Cooper Hewitt Electric Company, of Hoboken (Amer. Pat. 1,237,652, of Aug. 21, 1917), has devised new methods for stimulating various synthetic reactions, especially in the aromatic series, which under ordinary conditions take place sluggishly or not at all.

In carrying out the process use is made of certain energizing means such as electrically excited quartz tubes containing mercury vapor for producing radiation by electrical means.

The process is especially applicable in the case of substituting halogens for hydrogen in the methyl groups of toluene, xylene, etc. For example, to produce dibromo-xylene, bromine and xylene are mixed and under agitation exposed to the effect of the radiation from a quartz mercury vapor tube which catalyzes the reaction with a copious evolution of gaseous hydrogen bromide, the dibromo compound remaining behind. This process proceeds ordinarily only in sunlight and then very slowly. By use of the radiation from a quartz lamp, catalyzing takes place with tremendously greater rapidity and certainty.

Various convenient forms of apparatus for the purpose are described. Tubes of quartz surrounded with vacuum jackets and provided with agitators are especially valuable. In these it is possible to subject a reaction mixture to actinic rays from a source which generates more heat than desired for the reaction and protect the mixture from undue heating by the aid of a vacuum chamber.

Catalytic Production of Aromatic Amines

Otto Schmidt and Hugo Blankenhorn, of Mannheim, Germany, Assignors to the Badische Anilin & Soda Fabrik (Amer. Pat 1,237,828, of Aug. 21, 1917), have perfected a method for the catalytic manufacture of aniline and its homologues, which is, apparently, a notable simplification of the current processes for the reduction of aromatic nitro compounds.

It consists essentially in treating the substance to be hydrogenated, in the presence of a contact mass, with a mixture of water gas and at least one volume of water vapor, for each three volumes of the carbon monoxide present. Gases containing carbon monoxide and hydrogen, such as water gas, or Dowson gas, may also be used in the presence of water vapor, the reducing action of the hydrogen being increased by the simultaneous action of carbon monoxide and water vapor. The process renders it possible to substitute for hydrogen cheap carbon monoxide or the still cheaper mixtures containing it.

Hydrogenizations of the most varied kinds can be carried out by this process and the reaction takes place at comparatively low temperatures.

The transformation of nitrobenzene into aniline is effected as follows:

A vertical cylinder is supplied with a contact mass containing copper, such as is obtainable by coating 130 parts of pumice stone with a mixture of 24.3 parts of cupric carbonate, 2.7 parts of zinc carbonate and 20 parts of a concentrated sodium silicate solution and reducing at a low temperature. Through this cylinder is passed a mixture of vaporized nitrobenzene and an excess of a reducing gas, containing carbon monoxide and water vapor, in such a proportion that at least one volume of water vapor is present for each three volumes of carbon monoxide. A temperature of 200° to 220° C. is maintained during the reaction. The output of aniline, thus produced, is very satisfactory.

Manufacture of Trinitrotoluene.

Ferdinand Quartieri, an Italian chemist, of Milan (Amer. Pat. 1,241,017 of Sept. 25, 1917), finds that trinitrotoluene of exceptional purity can be secured if the crude dinitrotoluene obtained by gradual nitration be purified before proceeding to the final nitration. For this purpose the solid crude dinitro compound is submitted to a partial and fractional liquefaction. The resultant liquid, containing the impurities present, is removed and nitrated separately to produce a new amount of crude dinitro body. The residual purified dinitro-toluene is nitrated at 110° C., and yields a very pure trinitrotoluene. After slow crystallization, washing with water and removal of volatile impurities by heating in a vacuum, it possesses a melting point of 80.5° C. All necessity of recrystallization from volatile solvents is obviated by this method.

ARTIFICIAL COLORS

Reinstatement of the Dyestuff Industry in England.

By Professor Arthur G. Green.

Professor Green, the leading color chemist in Great Britain, has recently published a careful analysis of the dyestuff situation in England, and of the conditions requisite for the successful expansion of the industry and its permanent continuance after the war, which is full of valuable suggestions for those engaged in creating the American industry. Emphasis is laid upon the imperative necessity of favoring legislation if the British industry is to cope successfully with that of Germany later on. In this respect the American color manufacturer is fortunately well protected by the Congressional enactments of Sept. 8, 1916. Another point brought out by Professor Green is the necessity of having trained chemists among those in responsible charge of color industries. Here, also, it can be claimed that the leading factors in the American industry are making the right start.

The very considerable progress which has been made during the war toward the establishment of the British dyestuff industry upon a larger and firmer foundation, lends support to the hope that our lost prestige in this important industry may eventually be repaired. At the same time it is essential that we should not take a too optimistic view of the situation.

In this industry the possession of large capital, though of importance, is only a secondary asset. What may be termed the "intellectual capital" of the firms has by far the greatest value. Although, through patents and other publications, most of the manufacturing processes, so far as relates to their principles at least, are known to all, it may be safely asserted that not 1 per cent of such processes, if carried out strictly as described, would be capable of meeting competition under normal conditions. A deficiency, for example, of 5 to 10 per cent in the yield would be enough to make competition impossible. To work out so many processes in detail involves immense staffs of research chemists, and the formation of such staffs is the first task.

It is stated that the combination of the three German dyestuffs firms—Badische Aniline Company, Farbenfabriken, Elberfeld, and Berlin Aniline Company—employed in 1912 over 700 qualified chemists, mostly of university education. The preeminence of Germany in the organic chemical industry has been secured, not so much by the brilliant discoveries of a few men of outstanding originality and genius, as by the organization of armies of research workers, ready to carry out the ideas of their directors and to investigate in every possible detail any new reaction which may have been discovered. To establish the color industry in this country on a footing commensurate with that of Germany and able to compete with the latter in the free markets of the world will eventually necessitate the chemical staffing of our works on a similar scale. How shall we obtain these men? The number of organic chemists at present turned out from our universities and technical schools is very inadequate, the unpromising career offered in the past by the English dyestuff and other chemical industries having discouraged many men of ability from entering the chemical profession.

In the attempts which have been made during the war to stimulate the dyestuff industry by government assistance the mistake has been made of regarding the matter as a purely financial one. It was thought by those who had the direction of the project that a large dyestuff industry could be established in the country by the same method as might be adopted to put up a new cotton mill or to build a steel works; viz., to provide sufficient capital for the undertaking, for a board of directors consisting of business men having no expert knowledge, and leave them to engage the necessary chemists and engineers. Such a method, however, cannot succeed with the dyestuff industry, in which it is of paramount importance that the scientific direction should be at the top, and that science should not be merely employed as a hand-maiden to wait upon business. It can readily be demonstrated that the success attending the large German works was largely due to the fact that their chief directors were themselves men of good chemical and general education, and that not only the technical, but to a large extent also the business, policy of the firm was administered by chemists.

It would be easy to mention several of Germany's best known business men who are chemists by education and profession, and this should controvert the prevalent fallacy that a scientific training is a bad preparation for a business career. This system made for a wider outlook and enabled the leaders of the industry to take a longer view. They brought a degree of scientific imagination into business which enabled them to see beyond immediate financial returns to a more distant period when the bread which they had passed upon the waters would return to them tenfold. Whatever we may think of German business methods in other directions, the far-seeing policy of these men is worthy of the greatest admiration and imitation. In following the rise or subsequent decadence of the dyestuff industry in our own country, it is interesting to observe that a connection may be traced between the prosperity of the industry and the extent to which it was under chemical management. The English works, like the German, were originally founded by chemists, but in most cases the management, for one reason or other, subsequently passed into the hands of purely commercial men. Coincidently with this change the fortunes of the respective firms began to decline. To take a single example, with the history of which the writer is especially familiar: The firm of Simpson, Maul & Nicholson (the predecessors of Brooke, Simpson & Spiller) was founded and managed by E. C. Nicholson, a chemist of remarkable power and ability. Upon his retirement the business was bought by Messrs. Brooke, Simpson & Spiller, only one member of which firm was a chemist. After a short period of great prosperity, due to the pre-occupation of Germany in the French-German war, the business began to decline. During this period of temporary prosperity, in which enormous profits were earned, no attempt was made by the firm to provide for the future by engaging more chemists or by the establishment of larger research laboratories.

On the contrary, the business was awakened by the withdrawal of all the profits made, so that on the return of the German firms to active competition the business began to go down hill rapidly. Even the discovery of a number of important new reactions and new dyestuffs within the firm's laboratories did not avail to save them from decadence, for their commercial and unscientific management was so incapable of seeing the value of any innovation that they refused to take advantage of their own chemists' discoveries, which, in consequence, only served to benefit their German competitors, who so quickly made effective use of them. As examples may be mentioned the late Professor Meldola's discoveries of the preferential reduction of the nitro group in azo compounds as a means for preparing diazo dyestuffs; his discovery of fast blue, the first dyestuff of the oxazine series; the writer's discoveries of the primuline dyestuffs; the fixation of colors on the fibre by diazotization and coupling, and the yellow dyestuffs subsequently known as thiazol yellow and thioflavine T. These and other discoveries, the importance of which the German firms were quick to recognize, were made in the Hackney Wick laboratories between the years 1878 and 1888, but, through the absence of expert chemical knowledge in the directorate, brought neither profit to the firm nor encouragement to the inventor.

I think we may congratulate ourselves on the fact that in Manchester at least the rejuvenated industry is in no danger of suffering from this fault.

The position of the dyestuff industry of the world after the conclusion of peace is a difficult one to forecast. On the one hand, the German firms have by means of their big production of explosives strengthened their financial position and increased their dividends. On the other side, their plant must have been greatly disorganized and their staffs depleted by the war, and it will be some considerable time before they can again be brought to their previous state of efficiency. Further, whilst on one hand the world's stocks of dyestuffs have been largely exhausted and a free market will exist for a time, this will be of a temporary character only, as the permanent markets for German products will be greatly restricted, owing to the growth of competitors in all large industrial countries. The position is also complicated by the fact that in England, France, and America enormous explosive works have arisen which look to the manufacture of intermediates for dyestuffs as an outlet for the employment of their plant and organizations after the war. As, however, most of these plants are only adapted for the manufacture of a few products, such as nitrophenol, dinitrotoluol, aniline, toluidine, etc., and the quantities of these materials which they could produce would enormously exceed the demand, a large over-production of such products seems inevitable, and the largest of such concerns may therefore seek an outlet for their productions by themselves entering the dyestuffs arena.

It is obvious that the difficulties under which the English dyestuff industry must labor for a time can only be met by some measure of State assistance. Whether such assistance should take the form of an import duty, of a direct subsidy to the producer, or in a complete or partial prohibition upon imported dyestuffs, is a matter open to great differences of opinion, and one which I do not propose to discuss here. Without such help, however, during its period of growth, the reinstated dyestuff manufacture cannot establish a satisfactory position, even although, as may well be the case, the German industry does not regain its pre-war efficiency for several years.

The enormous importance of dyestuff manufacture to the country, which the war has demonstrated, will have convinced everyone that whatever means be adopted, this essential industry, with which so many other trades are inter-related or dependent, must never again be allowed to languish.

Japan's Purchase of American Dyes.

It is reported that the Japanese Government, at the end of September, purchased from the National Aniline and Chemical Co. artificial dyestuffs, valued at over $500,000. Immediate delivery was stipulated and within three days after closing the contract a large share of the colors started on their voyage westward. Prices ranged from $1.50 to $3.50 per lb. This is stated to be the largest individual sale of coal-tar colors ever made in the American market. It speaks volumes for the swift expansion of the American dyestuff industry that such a transaction could take place at this date. Probably a large share of the colors sold are blacks. It has been evident for some time that the point was being approached at which the output of black dyes in our works was not far removed from the current demand. In the matter of vegetable dyes, it has been possible for over a year past to ship abroad enormous amounts of these colors, without materially curtailing the quantity required in our domestic industries.

The Revival of the French Dye Industry

In a pamphlet written by M. Henry le Wita, and recently published at Paris, the author refers first of all to the great decline in the French chemical industry in general and the dye industry in particular. At the beginning of the 19th century France was well prepared for industrial developments. She had a brilliant group of scientists, headed by Lavoisier and his school, whose researches were of inestimable value to the French chemical industry. Subsequently, however, manufacturers were content to rest on their laurels, and supremacy in the chemical trades quickly passed to France's neighbors, notably Germany. Notwithstanding the latter country's concentration on the industrial applications of chemical science, the author points out that pure science was by no means neglected; on the contrary, it was regarded as supremely essential. The author gives fifteen reasons for the great success achieved by the German chemical industry. Practically all these reasons are now, after three years' war experience, sufficiently obvious and need not be repeated.

In the second chapter of his pamphlet, Le Wita points out that, despite innumerable speeches, addresses, and lectures, no action was taken in France to remedy matters until recently, when the French National Dyestuff Company was formed in Paris with a capital of 40,000,000 francs. This action followed the delivery of a lecture at Lyons by the French Minister, Denys Cochin, in February of the present year. The author also describes the energetic measures taken by the German dye trade to meet after-war conditions and the consequent formation of a gigantic combine with a total capital of three to four hundred million francs. In order to counter these measures on the part of Germany it is necessary, the author thinks, to refrain from any commercial relations with Germany and to manufacture as much as possible at home. The French National Dyestuff and Chemical Company requires, among other essentials for success, a Board of Directors containing real live men of affairs having a thorough knowledge of pure and applied science, also a complete absence of petty jealousy and friction in its working. One of the things which the company will have to undertake immediately is the working of the German dye factories in France, which have now been sequestered.—The Chemical Trade Journal.

The Swiss Dyestuff Industry in 1916

A report from the American Consulate at Basel furnishes some interesting data on the status, during 1916, of the Swiss color industry, which is confined almost entirely to the large works located in that city:

"There was a decrease in exports of aniline colors to the United States in 1916 amounting to 78,522 pounds, or 6 per cent, and an increase in value of $1,124,031, or 113 per cent. This was due to the general advance in prices and to the exclusive shipment of the finer and more expensive colors. The progress made in the American color industry practically excluded the lower grades of Swiss dyes from that market. Anxiety was felt in Switzerland concerning the future trade in Swiss colors with both the United States and England. The belief that those countries would not be able to produce aniline dyes was disproved. Since 1914 dye factories have also been built in France, Italy, and Russia. It became more and more difficult in 1916 to obtain necessary raw materials from England and the United States. Another cause of alarm to Swiss color manufacturers was the merger of two large groups of dyeworks in Germany with a joint capital of $230,000,000, with the object of capturing neutral markets after the war. The Swiss manufacturers are now preparing to withstand the apparently concerted effort of German color manufacturers to undermine the Swiss dye industry.

"To meet their immediate needs in raw materials, not provided for under an agreement with the British Board of Trade, the local manufacturers organized a syndicate, called the 'Verein Basler Chemische Fabriken,' under the Swiss Import Trust.

"The quantity of artificial indigo exported to the United States in 1916 declined by 212,521 pounds, but was valued at $150,229 more than that shipped in 1915. That there was an actual increase in value is unlikely, but the new tariff law making this color dutiable compelled the manufacturers to state the market value, whereas formerly, under free entry, they gave only nominal values in their invoices. The decrease in quantity should probably be attributed to the activity of the British firm at Ellesmere Port, which produced a great deal of artificial indigo in 1916.

"The trade in extracts became normal again last year. Long-delayed shipments of China galls were received and utilized in the factories. Both logwood and yellow wood were imported in sufficient quantities to meet the demands of the manufacturers."

Japanese Dyestuff Industry.

The manufacture of coal-tar dyestuffs in Japan has now reached the point at which apparently the domestic demand for certain staple products is fairly well met. The Japanese Government is now issuing permits for the export of sulfur black, aniline salts and certain alizarin colors. It is announced that shortly other products will be added to the list. There is evidently an effort to protect the reputation of the dyes exported from the island kingdom. Samples must be submitted for examination by Government analysis before permits are granted.

Japanese chemists while building up the new national dyestuff industry, contend with numerous handicaps in the matter of supplies and equipment. The "Nippon Dyestuff Manufacturing Co." has issued its third balance sheet, showing a deficit of $15,000. There is, however, an annual subsidy to the company, from the Japanese Government amounting to about $60,000.

British Exports of Dyestuffs and Coal-Tar Products.

During the month of July, 1917, the United Kingdom exported dyestuffs valued at $678,000 as compared with $403,000 in July, 1916. Coal-tar products, not dyes, were valued at $1,699,000, as compared with $1,015,000 for July, 1916.

NATURAL DYES

Preparations for Indigo Fermentation Vats.

Dr. A. Schmidt, of Höchst-on-the-Main, Germany (Amer. Pat. 1,239,526, of Sept. 11, 1917), has devised a class of stable, concentrated preparations for indigo fermentation vats, which may be of material value in connection with dyeing processes involving the use of indigo, as well as useful in the studies, now being carried on in India, to standardize the manufacture of natural indigo. The nature of these preparations is seen from the following statements:

The action of the so-called "cold oriental indigo vats" is due, for the most part, to phenomena of fermentation. They are caused by bacteria which require for their existence and growth nitrogenous nutrient media and consequently it has been found that by adding fermentable but not non-nitrogenous bodies, such as glucose, cane sugar, starch, etc., a cold fermentation vat cannot be satisfactorily started and continuously kept working. In practice there has already for a long time been used as "fermentable materials" as they were called, besides syrup, starch, glucose, etc., also bran, which contains vegetable albumin, i. e., nitrogenous material. It has been attempted to mix stable-indigo and indigo-white pastes with "vat-fermentation agents" with the addition of alkalis in order to convert them thereby into a stable form. Thus, according to a well known process 200 parts of indigo are made into a paste with 100 parts of wheat flour, 50 parts of syrup, 10 parts of quick lime and 540 parts of water. This process shows, however, the disadvantage that the paste thus obtained becomes putrefied and ferments as soon as the alkaline reagent disappears for some reason, for instance in consequence of the lime being consumed by the carbonic acid in the air.

The inventor finds that stable concentrated albumin preparations can be obtained which retain their action in the cold indigo fermentation vat, by mixing isolated albumin substances with water-soluble carbohydrates, for instance with molasses, glucose or the like, or with equivalents of water-soluble carbohydrates of high concentration, for instance glycerin. Thus valuable stable albumin-preparations are obtained either by mixing a concentrated water-soluble carbohydrate, for instance with the moist extract containing a high percentage of albumin (gluten), obtainable by extracting or boiling bran or an albuminous seed with water and, if required, subsequently evaporating; or, for instance, with other albuminous substances (albuminates), such as vegetable casein, casein or the like and also with albumoses, peptonoid products or the like. The high percentage of sugar causes preservation of the albuminous material in spite of its containing water and the sugar itself serves then as one of the fermentation agents in the vat. By such preparations it is possible to start well the so-called cold lime-fermentation vat and to keep it working. The indigo vats prepared with such albuminous and sacchariferous products show a much better condition than those prepared for instance with glucose alone; the deposit of the vat, when agitated, shows a pure yellow color which is not the case with the ordinary glucose-lime vat: the vat has not so great a tendency to deposit, etc., and works in many respects better than the ordinary glucose lime vat owing to the albumin it contains.

In making such concentrated albuminous-carbohydrate preparations there may be added, besides the bacteria contained in the albuminous raw products themselves, other materials containing bacteria, such as finely cut hay, or hay-tea, or portions of a fermentation liquor of lactic acid or butyric acid.

On mixing indigo or indigo white with such preparations, and evaporating to dryness, stable products are obtained, capable of preservation and available for use at any time in starting a cold fermentation vat.

Vegetable Dyes in the Philippines.

In a recent report the Philippine Bureau of Science states that probably more than a hundred species of plants containing valuable color principles are found in the islands, and many more could be readily cultivated. In most cases the colors produced are inferior in quality, being either fugitive or lacking in brilliancy. As the plants that yield dyeing materials grow wild and often are widely scattered, the supply is unreliable and insufficient. Little has been done towards developing the manufacture of local coloring materials, and until there is an intensive cultivation of the necessary plants, and the capital necessary for the enterprise can be secured, there is little prospect of commercial success.

Only two Philippine dye plants are commercially important. These are indigo and sappan or sibucao. Others are used locally, but scarcely enter into domestic commerce, much less into the external commerce of the Archipelago.

Sappan or sibucao is a shrub or small tree, widely distributed in the settled areas of the Philippines at low and medium altitudes. It is not systematically cultivated, but in a few districts, such as Guimaras Islands and parts of Panay, it is found in great abundance. In general, it appears only as a widely scattered tree. The wood is annually exported in considerable quantities to China.

Exports of sappan wood from the Philippines to China and Hong-Kong in 1914 amounted to 2,137,000 pounds, valued at $9,400.

The wood yields, an extraction with water, about 2 per cent of coloring matter, essentially the same as that obtained from the Brazil wood, Pernambuco wood, Lima wood and peach wood of South and Central America. All contain brazilin, $C_{16}H_{14}O_5$, closely related by constitution to haematoxylin. Brazilin is destitute of color but dissolves easily in alkalies, yielding a red solution. This, on exposure to the air, oxidizes to brazilein, $C_{16}H_{12}O_5$, which possesses vivid tinctorial properties. It is used to some extent in cotton dyeing and calico printing and occasionally on wool, chiefly in connection with other dyes. The brighter lakes with aluminum mordants find a limited use. The dye is quickly affected by light and washing. The extraction is not carried on in the Philippines, but in the countries importing the wood.

Indigo, locally known as tayum, tayom, tagum, pouay, tayum-tayum, and tagung-tagung, has been in the past extensively cultivated in some parts of the Philippines, and the prepared product entered extensively into the export trade. With the development of the coal-tar dye industry and the manufacture of artificial indigo, however, the production of indigo as a commercial crop in the islands practically ceased. It is still cultivated on a small scale in some parts of northern Luzon, but only to supply a limited local demand. It is highly probable that the extraction of natural indigo might be profitable at present, but the rehabilitation of the industry would take time and a considerable investment of capital in extraction vats. With the practical certainty that at the close of the war the industry would suffer from the competition of synthetic indigo, there seems to be no inclination to take risks.

Brown dyes are obtained from numerous plants, chiefly from the shrub or small tree known as bancudo or nino (Morinda indica, Linn.) certain of the mangrove trees, such as ceriops and bruguiera, the bark of xylocarpus (tabigue or nigui), and from numerous others less important sources. Bancudo is the well-known al dye of India. Cotton mordanted with tannin is colored dark red with this material.

Black dyes are secured from Herritiera litoralis, a common coastal tree, and from some species of Hibiscus, Semecarpus, Terminalia, and Diospyros. The determining factor in most cases is the presence of tannin in large quantities.

Yellow dyes of minor importance are secured from the seeds of Bixa orellana (annatto; from the wood of nauclea (baucal); from Carthamus tinctorius (safflower) which is occasionally cultivated as a dye plant; from the bark of the common mango; from some species of Vitex (molave); and from ligtang, a woody vine having yellow wood rich in berberine.

Seaweed as a Dyestuff

Public interest in the United States has been centered upon seaweed as a prospective source, on a large scale, of potash salts. In other countries the utilization of the material has been studied with much greater care and minuteness. The Japanese manufacture from seaweed some 27 different commercial products. In Europe, seaweed has been used for various purposes in the textile trade for many years, and several patents have been taken out concerning several departments of the industry in which it has proved to be of assistance. For instance, in 1881, C. V. Stanford patented a process for obtaining algin from seaweed, to be used as a dressing and for finishing textiles, as well as a thickening for coloring matters. In 1902, J. Y. Johnson patented a process, whereby laminaria from seaweeds could be employed as an inert medium for packing and transporting indigo.

In a recent patent, taken out by N. Malcolmson and H. Kelsey, a method is described for directly employing various groups of seaweeds for the production of dyestuffs in the form of paste or powder.

The Melanospern, Rhodospern, and Chlorospern groups contain pigments of various colors. Certain colors are remarkably constant in large natural algæ groups. Thus, the Fucaceæ exhibit a brown or olive color, and the Florideæ a beautiful rose-red. To obtain the coloring matter, the seaweed is boiled until it has become soft, after which it is crushed to form a paste, or the seaweed may be roasted and ground to form a powder. The dye liquid is made up of equal parts of powder or paste and sulfuric acid, say 1 oz. dissolved in 1 gallon water. The colors imparted to the fabrics are fast, and do not necessarily require the use of mordants. The seaweed dyestuff can be used along with other dyestuffs in mordants, liquors, or topping baths, to give a variety of shades.

The seaweed can also be used raw, that is, put into the bath along with the fabric to be dyed and boiled with it, using 1 oz. of seaweed per lb. of fabric. This process, however, requires much boiling, and is not as satisfactory as when the seaweed has been previously prepared.

The Dyeing of Chinese Rugs.

American lovers of oriental rugs are becoming increasingly familiar with the products of Chinese looms. The methods of dyeing the yarn used in these rugs are exceedingly primitive, but the colors obtained are exceptionally fast. The following account of the materials employed and the method of application recently appeared in "The Dyer and Calico Printer," and is of general interest:

The wool that enters into Chinese carpets is grown in Mongolia, and the yarn is spun by old men and idle women in the border villages. Each spinner strolls about with a wad of raw wool and a hand spindle, and accumulates a ball of yarn by a mechanical twirling of the spindle while entering vigorously into the gossip of the day. As no shuttle is used in the weaving of the carpets, so there is no wheel used in the spinning of the yarn. The Chinese rug is most literally hand-made.

The Ninghsia dyes never fade, but gain in lustre as they age. A twenty-four-year-old carpet, far from being worn out, has a silky brilliance and gloss which cannot be imitated. The native dyes used in Peking, when properly set, will outlast the carpet, and nothing has yet been discovered in China which will bleach the rug without ruining the carpet, if the dyer has done his work conscientiously. Actual experiment has shown that it is possible to boil a new rug to shreds without extracting the dye out of the yarn.

Each rug maker does his own dyeing to match the colors in the design submitted to him. At one dyeing he makes enough to finish the carpets, so that there can be no possible variation in shade, and he has his whole supply of the various colors dyed, set and dried, ready for the client's inspection before he sets his men to work on the loom. Minerals are rarely used. Their blue is indigo; the locust tree, which also yields black; brown comes from a kind of acorn husk; purple from hollyhocks: and yellows, reds, greens and other shades from various native woods, mostly cheap and abundant.

The dyer takes as much dyewood or seed as his judgment prompts him to use, throws it into a great pot of boiling water, and when the liquid takes on color throws in the yarn, and sets a man to stir it. The fixing of the colors is done with alum. A rug made partly with yarn dyed with the native vegetable dyes and partly with aniline dyes fades in streaks and patches, and betrays itself in a few months, but the colors in a well-dyed Peking rug temper evenly and bear any amount of washing. Strong soap and water have no more effect on a good rug than they have upon a good handkerchief, and often make a surprising difference in the ornamental qualities of a carpet that appears hopelessly old and dirty.

The recent carpet boom has made the Chinese carpet an article of trade, and has given it the status of a useful and ornamental floor covering. The successful buyers in the carpet centres have worked hard to impress their ideas upon the native artists, with the result that the Chinese are developing a perception of color and arrangement as the foreigner sees them, and are relegating their old patterns to the dust-bins.

Chinese Indigo.

A consular report states, that the cultivation of indigo has been notably augmented in the Swatow district, China. The export of crude indigo, in a paste form, increased from 1,683 short tons in 1913 to 5,388 tons in 1916. The dyestuff is sent chiefly to other parts of China, and also to Siam and Singapore. The methods of extraction employed are much cruder than those used in India.

Dyestuffs Used in Japan.

A leading Japanese merchant, now in New York, states that about one half of the dyes, now currently employed in Japan, come from American manufacturers. The remaining half are of domestic make. The latter fail, thus far, to approach the American standards of strength and purity.

SYNTHETIC DRUGS AND PERFUMES PHOTOGRAPHIC DEVELOPERS

The Role of Saccharin During the War.

In company with a few other coal-tar compounds, such as phenol, picric acid and trinitrotoluene, saccharin has come to occupy a position in the forefront of the chemical stage during the world war. The *Oil, Paint and Drug Reporter,* in its issue of Sept. 24, furnishes an exceedingly interesting portrayal of the record established by this product,—one of the very few industrial coal-tar compounds originating in the United States:

"The exigencies of the present war have been responsible for the rise to prominence of many items which prior to the new demands incident to changes in consumption were at most little more than torpid. The chemical and drug markets include many commodities which have seen violent fluctuations in price, because of increased demand and decreased output, but there have been few which have established such a record as saccharin.

"During the period of general world normality prior to the first movement in the direction of a general world conflagration, saccharin, while in steady demand for certain medical and technical uses, did not, save in some isolated cases, enter into general consumption. It is true that in several European countries there was a limited demand for this product of the laboratory as a substitute for beet or cane sugar, but such use was forbidden in the United States.

"With the carrier shortage incident to the establishment of embargo lines and neutral zones, the unavailability of shipping to transport sugar to the Continent, the labor scarcity and the need for the tillable land for foodstuffs on the Continent—all of which meant extremely high prices for cane and beet sugar because of high freights, insurance, etc., when the sugar could be obtained—the consumption of saacharin increased enormously. Even in Germany, where the beet sugar output has been enormous in the past, the change to this coal-tar derivative has been made to a considerable extent: and in Russia, Sweden and Norway such a demand has been created that special trips to the United States have been made by individuals, who have bought saccharin here in the open market, paid the necessary duty and taken the chemical sweetner back with them for sale at a notable profit.

"The result of this changed consumption has been a remarkable increase in the prices paid in the markets of this country. It is estimated that of the total amount sold in American markets during the past six months 75 per cent. at least has been for foreign consumption. The fact that saccharin is approximately 500 times sweeter than sugar makes it possible to ship by parcels post and in small packages an amount which, while not large in bulk, equals a sugar tonnage that it would be impossible to transport, with resulting tremendous saving in the item of freight alone.

"An idea of the demand for saccharin can be gained from the following comparison of price quotations in the New York market, from July, 1914, to date, the figures showing the high and low for the year. with the exception of the first price, which was for the month prior to the declaration of hostilities:

Year.	Range.
1914 (July)	$1.15@$1.25
1915	2.85@11.50
1916	11.50@21.50
1917	20.50@46.00

"The demand for saccharin in this market has been largely for immediate shipment, and while producers are making every effort to meet the demands, it has been found difficult to supply the requirements at short notice, and as a result the market has been in the hands of speculative interests to an unusual degree. The contract price today is nominally approximately $26 a pound, whereas for immediate shipment to Europe as high as $46 has been paid for the insoluble variety within the past week."

Enlargement of the Monsanto Works.

The Monsanto Chemical Co., of St. Louis, has been one of the leading factors in establishing in our country the manufacture of synthetic coal-tar medicinals. Its work in this field has extended so rapidly that the company now finds it necessary to enlarge its plant on a large scale. Plans have been completed for the erection and equipment of additional buildings on the Illinois bank of the Mississippi, opposite St. Louis, which involve an outlay of $1,500,000. The company hopes, in its enlarged quarters, to be able to so expand its production of various synthetic drugs that the United States can be permanently freed from dependence upon the European sources from which they have hitherto been chiefly obtained.

Army Supplies.

The Field Medical Supply Depot of the American Army is laying in extensive quantities of drugs for the forthcoming campaign. In its latest call for bids, among several hundred items, were nearly

5 tons of phenol in ½-lb. bottles, 7,500 bottles of acetyl-salicylic acid, each bottle containing 500 tablets, 5,250 bottles of salicylic acid and 15,500 bottles of sodium salicylate.

MISCELLANEOUS

The Federal Dyestuff and Chemical Corporation.

Receivers have been appointed by the Federal District Court to take over the affairs of the Federal Dyestuff and Chemical Corporation. This company was organized in 1915 with an exceptional amount of capital and plans were made for a varied and extensive range of manufacture, covering a large number of coal-tar colors and the chemicals required in their production. During 1916 very large blocks of stock were offered for sale, and the transactions assumed dimensions unusual in connection with companies engaged in the manufacture of colors.

The company has a floating debt of about $400,000 and $2,000,000 of first mortgage 6% gold notes are due June, 1918.

The plant at Kingsport, Tenn., including buildings, land and equipment, is valued by the management at $4,000,000. In addition stock on hand, including raw materials, finished product and semi-finished product is valued at $800,000 to $900,000. Last year the corporation did a business of approximately $2,000,000 of which $400,000 to $500,000 represented profits. It is stated by the management that this profit, under the arrangement by which the company was financed, was not at present available for interest or dividends.

The plant is equipped to manufacture a large variety of colors, but its full possibilities have not yet been utilized. Production is confined to a few dyes, chiefly sulfur colors, and some staple chemicals.

The receivership is a friendly one and the officers of the corporation feel that there is no reason to fear the outcome if the company is permitted to keep going.

Current Literature.

Color chemists will find matters of interest in the following articles, which have recently appeared:

"The Theory of Color Lakes," J. O. Baudisch, Z. Angew. Chem., 1917, 30, 133; abstracted in J. S. C. I., 1917, 36, 705.

Qualitative Spectrum Analysis of Organic Dyestuffs by Formanek's Method.

A careful review of the objections of Muller, Lefevre, Andre, Eijdman and Weigart, and discussion of the difficulties encountered in the use of qualitive spectrum analysis of dyestuffs by Formanek's method is given by J. Pokorny in the Journal of the Society of Dyers and Colorists of recent date. The two greatest objections, namely the optical errors, caused by contrast action and the displacement of bands in mixtures, are shown to be without just foundation. Mr. Pokorny highly recommends the spectroscopic method for the identification of dyestuffs as the result of long experience and especially because such simple apparatus is suitable. Chemical methods on rare occasions were employed to assist in identification.

(J. Pokorny, J. Soc. Dyers and Colorists, 1917, 33, 162.)

Intra-vitam Color Reactions.

N. A. Cobb, of the U. S. Department of Agriculture, is reported in Science (1917, 46, No. 1181) to have stated that if substances giving color reactions in living tissues could be applied to small transparent, varied and highly complex living organisms under circumstances that would permit microscopic examination while the reactions are in progress, it seems certain that important advances would be made in our knowledge of nutrition, growth and decay. Such conditions are realized by feeding coal-tar dyes to free living nematodes which constitute a group of hundreds of thousands of species and an inconceivable number of kinds of physiological action.

By using special precautions as to the kind of glasses in the microscope, in the preparation of the slide and the quality of the light for illumination and by using a great variety of coal-tar compounds, the author demonstrated the existence of an unsuspected number of kinds of "granules," functioning in different roles within the living cell.

Decolorizing Carbon.

The secrets of the decolorizing action and of the preparation of the Eponite and Norite, the two marvelously efficient carbon blacks made in Germany and the Netherlands, respectively (Nederlandsche Noritmaatschappij, Declora, Amsterdam), have been unraveled. After many experiments using different woods, pine, cedar, poplar, willow, treated or untreated with lime, magnesia, salts, starch, mucilage, at low and high temperatures, and water under all conceivable conditions, the results found were that charcoals from natural wood, without treatment, were useless as decolorizing agents, but woods treated with milk of lime or calcium acetate, carbonized at a white heat, gave charcoals more effective than eponite. Any porus wood gave an active charcoal.

The process used is as follows: Mix pine, willow or cedar sawdust with milk of lime to form a dough; heat to drive off some water and while still damp place in a crucible; cover with a layer of lime and raise nearly to a white heat. Cool, add water containing an excess of hydrochloric acid, boil, filter, wash with hot water, drain and heat in an iron retort to red heat. Finally powder to charcoal and sift through a 60-mesh sieve.

(Experiments of Royal Soc., Chem. Tr. J., 1917 61, 218, No. 1582.)

Utilization of By-Products.

An interesting discovery has been made and patented by a German chemist, Willy Moeller. The residual products produced in oil refineries by treatment of crude mineral oil with concentrated sulfuric acid, known as acid resins, constitute a troublesome waste. The patentee has found that these products contain substances—probably condensed sulfonated hydrocarbons, which possess in high degree the property of forming leather, that is, the acid resins after removal of the sulfuric acid constitute a very good tanning agent.

The acid mass is diluted with water and neutralized with an alkali, alkaline earth or their carbonates. The sulfate having been removed by crystallization or clarification, the liquor may be concentrated for market or diluted for direct use. The hides are prepared as for the usual tanning process and conversion of hide into leather can be made by the old pit process or in the tanning vat. The leather obtained has great elasticity and resembles chrome leather in its chemical properties.

(Willy Moeller, Ger. Pat., The Leather Mfr., 1917, 28, 247, No. 10.)

New Book on Color.

The latest work of J. W. Lovibond on "Light and Colour Theories and Their Relation to Colour Standardization" is concerned with those methods of analyzing, measuring and recording the colors of objects which have proved of practical value in industrial applications. The method of color matching by glass units in three primary colors, red, yellow and blue, is now a familiar one in trade, and has proved of limited but unquestioned value. The chapters in the new work take up various color theories, the evolution of the authors' method, the kind of light best adapted for color matching, the use of the term "specific color development," which is analogous to specific heat or specific gravity, and a method of tabulating all colors in three dimensions.

Fire in a Salicylic Acid Plant.

The large plant of the British-American Chemical Co., at College Point, L. I., was destroyed by fire on Oct. 13, the loss being estimated at $250,000. This factory was erected in 1916 by a competent London engineer, and has been an important factor in contributing to the domestic output of salicylic acid.

The fire had its origin in an explosion in one of the condensing systems, and there is no suspicion that it was due to any deliberate attempt on the part of those working in the interests of our enemies, as has been the supposed case in some of the conflagrations at works in the coal-tar chemical industry.

The Photometry of Luminescent Substances.

The measurement of the brightness of fluorescent and phosphorescent substances presents a large and valuable field for study since the present activity in night operations in war has caused a very great demand for self-luminous compounds. Arthur Blok discusses various photometric methods, the difficulties encountered, and other points of interest and concludes that those who are conversant with the better-known applications of photometry might well devote attention to the luminous phenomena shown by this class of substances.

(Arthur Blok, Sci. Amer. Suppl., 1917, June 9, No. 2162.)

The Century Colors Co.

A new organization, termed the Century Colors Co., replaces the Cassella Color Co., of Philadelphia, taking over the entire technical and sales staff of the latter company.

August Exports of Coal Tar Colors.

The exports of artificial dyes from the United States during the month of August were valued at $196,000, as compared with $497,000 during the preceding month.

Among the subscriptions to the second issue of the Liberty bonds was one of $500,000 from the National Aniline and Chemical Co.

Fire Destroys N. J. Chemical Works.

With a loss estimated at about $50,000, fire recently destroyed the plant of the Transatlantic Chemical Company, Linden, N. J.

To Manufacture Paints and Varnishes.

To manufacture paints, varnishes, etc., Slavin and Sipkin, Inc., Newark, N. J., have been incorporated with a capital of $10,000 by R. and I. Slavin and A. Sipkin, Newark.

New Chemical Firm.

Chemicals and kindred products will be manufactured by Webster & Company, recently incorporated at Philadelphia, Pa. The capital of the new firm is $50,000 and the incorporators are M. Mills, John Kearns and C. A. Murphy, Philadelphia.

Penman-Littlehales Improvements.

The Penman-Littlehales Chemical Company, Syracuse, N. Y., is preparing for the erection of additions and improvements to its works to the value of $25,000.

Chemicals and Minerals.

With a capital of $100,000, Miner-Edgar Co., Newark, has been incorporated to deal in chemicals and minerals. The incorporators are Henry M. Miner, James C. Thornton and N. M. Goodlet, Jr.

To Manufacture Lime and Potash.

The American Lime and Potash Products Corporation has been incorporated at Roanoke, Va., to manufacture lime, potash and their by-products. The incorporators are F. M. Hughson, Roanoke, and E. S. Hamilton, W. Va.

Divi-Divi	ton	65.00 —70.00
Fustic, sticks	ton	50.00 —53.00
Chips	lb.	.04½— .05
Hypernic chips	lb.	.09 — .10
Logwood, sticks	ton	38.00 —43.00
Chips	lb.	.03 — .03¼
Myrobolans	ton	60.00 —65.00
Quercitron Bark No. 1	ton	28.00 —31.00
No. 2	ton	20.00 —25.00
Red Saunders, chips	lb.	.15 — .17
Sumac, Sicily, 29 p.c. tannin	ton	87.00 —90.00
Virginia, 25 p.c. tannin	ton	50.00 —59.00

EXTRACTS.

Archil, double	lb.	.15 — .17
Triple	lb.	.18 — .20
Concentrated	lb.	.21 — .26
Chestnut, 25 p.c. tannin	lb.	.02¼— .02¾
Clarified, 25 p.c. tannin	lb.	.02½— .03
Cutch, Rangoon, boxes	lb.	.12 — .13
Liquid	lb.	.08½— .09
Tablet	lb.	.10 — .12
Cudbear, French	lb.	.70 — .80
English	lb.	.18 — .24
Concentrated	lb.	.75 — .85
Flavine	lb.	1.00— 1.50
Fustic	lb.	.13 — .16
Gall	lb.	.20 — .21
Gambier, 25 p.c. tannin	lb.	.10 — .10½
Common	lb.	.16 — .16½
Cubes, No. 1	lb.	.22½— .23
No. 2	lb.	.21 — .21½
Hematine	lb.	.09 — .10
Crystals	lb.	.20 — .28
Hypernic, liquid	lb.	— — —
Indigo, natural, for cotton	lb.	.50 — .54
For wool	lb.	.30 — .32
Indigotin, 100 p.c. pure	lb.	— — 5.50
Logwood, solid	lb.	.19 — .21
Crystals	lb.	.19 — .24
51° Tw.	lb.	.09½— .12
Myrabolans, 25 p.c. tannin	lb.	.06 — .07
Solid, 50 p.c. tannin	lb.	.10 — .11
Osage Orange—		
Powdered, Aurantine	lb.	— — .25
Paste	lb.	.06 — .12
Persian Berries	lb.	.20 — .25
Quercitron	lb.	.07¼— .08¼
Sumac, liquid, 25 p.c. tan	lb.	.06 — .10½

DYEING ACCESSORIES.

Acetic acid, 28 p.c	lb.	.05½— .07
56 p.c.	lb.	.11 — .12½
Glacial, 99 p.c	lb.	.35 — .45
Albumen, Egg	lb.	1.05 — 1.10
Blood, imported	lb.	.58 — .61
Domestic	lb.	.53 — .54
Alum, ammonium, lump	lb.	.04 — .04½
Alum, chrome	lb.	.25 — .28
Alum, potassium, lump	lb.	.08½— .09
Aluminum acetate	lb.	.80 — .90
Aluminum chloride, liq	lb.	.04½— .05
Aluminum sulfate, techn	lb.	.02 — .02¼
Aluminum sulfate, iron free	lb.	.03¼— .03½
Ammonium vanadate	lb.	7.00 — —
Bleaching powder, 35 p.c	lb.	.01½— .02
Borax, cryst.	lb.	.07¼— .07½
Citric acid, crystals	lb.	.72 — .72½
Powdered	lb.	.72½— .73
Copper subacetate(verdigris)	lb.	.40 — .42
Copper sulfate (blue vitriol) 99 p.c.	lb.	.09¾— .10
Dextrine, corn	100 lbs.	— — 7.00
Dextrine, domestic potato	lb.	.14½— —
Ferric sulfate, basic (nitrate of iron), comm	lb.	.01¾— .02¼
True	lb.	.07½— .08
Ferrous sulfate(copperas)	100 lbs.	1.00 — 1.50
Formic acid, 75 p.c	lb.	.40 — .45
Glauber's salt (sodium sulfate)	100 lbs.	1.20 — 1.35
Glycerin, C. P	lb.	.69 — .70
Gum arabic, firsts	lb.	.52 — .55
Seconds	lb.	.48 — .50
Sorts, amber	lb.	.34 — .35
White	lb.	.46 — .50
Gum tragacanth, Alep., firsts	lb.	2.30 — 2.50
Seconds	lb.	1.95 — 2.00
Thirds	lb.	1.65 — 1.85
Sorts	lb.	.75 — .90
Hydrochloric acid (muriatic) 18°	lb.	.01½— .02
20°	lb.	.01¾— .03
22°	lb.	.02¼— .03
Lactic acid, 22°	lb.	.05½— .06¼
44°	lb.	.15 — .16
Nitric acid, 36°	lb.	.07¼— .07½
38°	lb.	.06¾— .07¼
40°	lb.	.08 — .09
42°	lb.	.09½— .10½
Oxalic acid	lb.	.43 — .46
Potassium antimony tartrate (tartar emetic)	lb.	.59 — .60
U. S. P.	lb.	.62 — .67
Potassium bichromate	lb.	.45 — .46
Potassium ferricyanide (red prussiate)	lb.	2.90 — 3.25
Potassium ferrocyanide (yellow prussiate)	lb.	1.27 — 1.35
Potassium tartarate, acid (cream of tartar)	lb.	.52 — .55
Prussian blue	lb.	.80 — .90
Soluble	lb.	.95 — 1.00
Sago flour	lb.	.04¾— .05
Soda ash, 58 p.c.	100 lbs.	3.15 — 3.30
Soda, caustic, 76-78 p.c.	100 lbs.	8.10 — 8.30
Sodium acetate	lb.	.11½— .13½
Sodium bichromate	lb.	.19 — .21
Sodium bisulfite	lb.	.05¾— .06
Sodium chlorate	lb.	.23 — .24½
Sodium ferrocyanide (yellow prussiate)	lb.	.35 — .36
Sodium nitrite techn	lb.	.35 — .37
Sodium phosphate, com	lb.	.04½— .07
Sodium silicate, liquor 50 p.c.,	100 lbs.	1.10 — 1.25
Crystals	lb.	.03¾— —
Sodium sulfide, 60 p.c., fused	lb.	.03 — .03¼
Crystals, 30 p.c.	lb.	.02 — .02¼
Sodium thiosulfate (hyposulfite)	100 lbs.	1.60— 1.75
Soluble oil, 50 p.c.	lb.	.10 — .12
75-85 p.c.	lb.	18 — .20
Stannous chloride (tin crystals)	lb.	.41 — .41½
Stannic chloride (tin bichloride), 50°	lb.	.20¼— .21¼
Starch, corn, pearl	100 lbs.	6.30 — 6.48
Potato	lb.	.12½— .13
Rice	lb.	.08 — .10
Wheat	lb.	.05 — .06
Sulfuric acid, 60°	ton	25.00 —26.00
66°	ton	34.00 —35.00
Oleum, 20 p.c.	lb.	.02 — .02¼
Tartaric acid, crystals	lb.	.78½— .81
Turkey Red oil	lb.	.14 — .16
Zinc dust, 350 mesh	lb.	.18 — .25

IMPORTS AND EXPORTS OF COAL-TAR PRODUCTS AND NATURAL DYESTUFFS

The following is the Government report of imports and exports of these wares for the eight months ending August, 1915, 1916, and 1917, and for the month of August, 1916, and 1917.

IMPORTS

ARTICLES	AUGUST				EIGHT MONTHS ENDING AUGUST					
	1916		1917		1915		1916		1917	
Coal-Tar Products—										
Acid, carbolic ...lbs.	114,953	$8,397	132,704	$9,709	1,615,314	$91.852	1,583,359	$109,587	447,769	$36,063

ULTRA VIOLET LIGHT

Its Application in Chemical Arts

By Carleton Ellis and A. A. Wells.[*]

This Is the Eighth Installment of an Article Dealing with Investigations Conducted by the Writers Into the Possible Applications of Ultra Violet Light. The Present Installment Discusses Types of Apparatus Used for Sterilization and Other Purposes, Including Lamps Developed by von Recklinghausen, Keyes and Others. Part IX Will Appear in the December issue.

PART VIII

Types of Apparatus Used for Sterilization and Other Purposes.

Otto (French patent 421,296, Oct. 10, 1910) describes an apparatus consisting of a cylindrical vessel in the interior of which are placed clusters of lamps capable of emitting ultra violet rays. The water to be treated enters the cylinder at one end and leaves at the other. The lamps may be fitted into a movable chamber in the cylindrical vessel, so that faulty units may be repaired as required. The diameter of the cylinder may be reduced by means of plates at the points where the lamps are situated.

A mercury vapor lamp with quartz illuminating tube is described by *Gallois* (Bull. soc. encour. ind. nat., 121). In the initial position the mercury fills the illuminating tube, but when the current is started, a coil attracts an armature connected by a rod with the tube, and turns the latter on its axis about 40°, whereby in consequence of the shape of the tube the mercury is divided into two portions and an arc is formed across the intervening space. Quartz lamps are constructed to work under tension of 220 to 500 V., giving a candle power of 500-6600.

Quartz Filling.

Quartz pearls are recommended by Allgemeine Elektrizitats-Ges (German patent 283,484, May 20, 1913), as a substance which may be used for filling the space in which the condensation of mercury occurs in a high pressure mercury vapor lamp and which does not effect the working of the lamp. The pressure and therefore the candle power are thus claimed to be increased.

Cold Light.

A design of mercury vapor lamp yielding nearly cold light is described by *Daguerre, Medard* and *Fontaine* (Compt. rend. 157, 921-2, 1914), which is in the form of an inverted U-tube and is made of fused silica. Electrodes of invar enter the ends of the tube. A short intense arc is formed at the bend of the tube between the columns of mercury on either side. The lamp is enclosed in a transparent silica flask—the wall of which is paraboloidal and silvered to act as a reflector—and is immersed in a tank of water. The light is concentrated by the mirror and emerges through a silica window in the tank. The tank consumes 18 amperes either alternating or direct current at 70 volts and yields 3,000 candle power. The light is practically cold and can be used for microscopy and projection work without heating the specimens or celluloid films. It has the advantage over the carbon arc in that the luminous point remains fixed and requires no regulation. Its application to water sterilization and submarine photography is suggested.

Thallium and Caesium Lamp.

Cooper Hewitt (U. S. patent 1,197,629, Sept. 12, 1916) suggests the use of metals such as thallium and caesium in the manufacture of quartz mercury vapor lamps in order to increase the ultra violet efficiency. In the construction of this lamp, mercury is used in one end of the quartz tube and acts as the anode, while the other metal is placed in the opposite end of the tube and serves as the cathode. Inasmuch as thallium and caesium are solid at ordinary temperatures and difficulty would be experienced in starting the lamp, in case it were made in the same manner as a quartz mercury lamp, a connecting rod is inserted between the mercury and the cathode to assist in starting the lamp. When the heavy current is turned on the cathode becomes heated to such an extent that the metal becomes molten and partially vaporized, after which the operation of the lamp takes place in the usual manner.

Life of Lamps.

Evans (Trans. Illum. Eng. Soc., 8, 1913) describes in detail various types of quartz lamps and gives curves and drawings illustrating the principal electric and photometric characteristics. The average life of the 220 volt type is stated to be between 2,500 and 3,000 hours before being re-exhausted. Lamps can be re-exhausted about three times. The cost per 1,000 burning hours is estimated at $4 to $5. The applications of the quartz lamp to sterilization of water and milk, fixation of patent leathers, testing permanency of colors, etc., are discussed.

Absorption of Nitrogen.

In a method for improving the vacuum in electrical apparatus and more especially as applied to the quartz mercury vapor lamp *von Recklinghausen* (U. S. patent 1,110,576, Sept. 15, 1914) suggests the use of certain metals which have the property of absorbing nitrogen when heated to a high temperature. For this purpose magnesium, boron and titanium are proposed, the latter two being preferred. In the operation of this process the nitrogen occluding metals are introduced into the chamber in a solid or powdered form and means provided for raising them to the desired temperature. For example, in the construction of a mercury vapor lamp the nitrogen occluding metals are placed either in a small tubular projection blown in the vessel or they may be used in the form of bars and connected with an electric current. The mercury is placed in the chamber and the vacuum drawn in the usual way. Before setting the lamp in operation the nitrogen occluding metals are heated and in this manner the normal vacuum is increased. In case there is a leak in the vacuum seals allowing a small quantity of air to enter, thus decreasing the vacuum, it is claimed that the heat generated by the operation of the lamp will raise the nitrogen occluding metals to a temperature at which they will readily absorb the air which has entered the lamp due to leakage and thereby maintain the vacuum automatically.

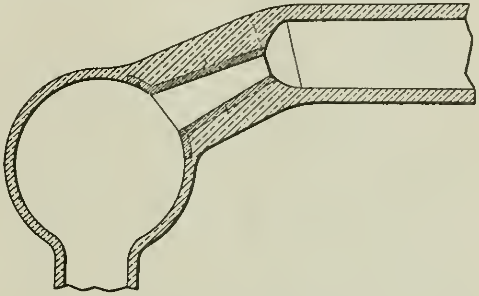
Von Recklinghausen Nitrogen-Absorbing Lamp.

Preventing "Cathode Spot" Deterioration.

The effective life of a quartz mercury vapor lamp is increased by von Recklinghausen (U. S. patent 1,188,587, June 27, 1916) by reinforcing the quartz tube at the points which are subject to the greatest deterioration. There is a certain spot in lamps of the usual construction which von Recklinghausen calls the "cathode spot," at which point the concentration of the current and the exceedingly high temperature produced have a tendency to disintegrate or otherwise injure the quartz surface. As a remedy for this, von Recklinghausen proposes to line this portion of the quartz lamp with a highly refractory material such as "titanium zircon quartz" and thus to greatly prolong the life of the lamp. Inasmuch as this "cathode spot" does not remain stationary but is advanced or retarded according to the workings of the lamp, quite a considerable portion of a constricted surface as well as a portion of the condensing bulb is lined with this material. It is claimed that cracking and clouding of the quartz is obviated to a great degree by this method of construction.

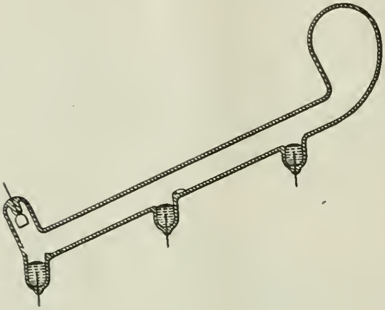


Von Recklinghausen Reinforced Lamp.

Mercury Distribution.

The proper distribution of the conducting fluid, in a mercury vapor lamp has been investigated by von Recklinghausen (U. S. patents 1,091,244, March 24, 1914, and 1,110,574, Sept. 15, 1914) who states that it is customary in some cases to use a series of electrodes in lamps of this type and that in these cases difficulty is encountered in maintaining the proper distribution of the electrode. In order to obviate these difficulties Von Recklinghausen proposes the inclining of the arc container, the condensing chamber being located at the top. The condensed metal flowing along the bottom of the tube fills each pocket in succession, the remaining metal overflowing and running along down the tube until the next electrode is reached. This pocket in turn is filled in case it is not already full, the overflow passing on to the next electrode. In an operation of this kind difficulty might be encountered, causing a short circuit, in case the entire bottom of the tube was covered with a stream of mercury. If, however, a weir is placed at the upper edge of the electrode pocket, the mercury will accumulate and flow intermittently from one pocket to the next, thus breaking any contact which might otherwise be formed. (See cut at top of page 30.)

Another type of apparatus using the same method of maintaining the mercury distribution consists of an arc container having two tubular extensions on the bottom side which dip into vessels containing a supply of mercury. These two vessels are connected by means of a small pump in order to transfer mercury from one vessel to the other. The positive pole is connected through one of these containing vessels, the negative pole being connected to the quartz chamber through an electrode pocket. As the metal is vaporized it condenses and flows into the electrode pocket and from here overflows and runs down into one of the chambers. Any excess or deficiency of mercury may be corrected from the receiving vessels. As in the previous type short circuits are prevented by placing obstructions just in advance of the electrode pockets.



Lamp with Arc Container Inclined.

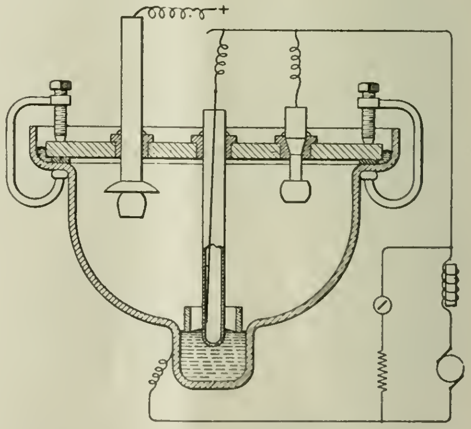
"Negative Electrode Flame" Effect in von Recklinghausen Apparatus.

In the construction of a vapor electrical apparatus, especially of a larger type, von Recklinghausen (U. S. patents 1,110,572, 1,110,573 and 1,110,575, Sept. 15, 1914) makes use of a metal chamber in which the negative electrode is in contact with the chamber and the positive electrode insulated away. Where an apparatus of this type must be maintained under high vacuum, difficulty is likely to be encountered. The mercury which is used as an electrode is contained in a small pocket located at the bottom of the chamber and the positive electrode, which may be of iron, is suspended through the cover. In operation, in case the vacuum becomes slightly imperfect, mercury tends to collect on the insulating tube and eventually cause a short circuit. This is obviated by carrying the temperature to such a point that the insulating tubes or a portion of them are heated to such a temperature that condensation is impossible. Another danger which is likely to occur is the "negative electrode flame," which has a tendency to attach itself to the solid portions surrounding the negative electrode, thus causing disintegration. In order to obviate this, von Recklinghausen inserts a porcelain ring in the cup containing the mercury, thus preventing the flame from attacking the metal. The material used in packing the joints of the vessel must be free from carbon, otherwise a small amount of carbon may enter the chamber and cause considerable injury. If, for example, asbestos is used, care must be taken that any binding material, such as rubber, be carefully burned out before use

R. U. V. Apparatus.

The ultra violet lamp used by the R. U. V. Company* is a clear quartz lamp and is produced for 110-volt and 220-volt direct-current operation, the 220-volt lamp being richer in ultra violet light than is the 110-volt lamp. Ultra violet rays range from 0.40u down to 0.10u; practically, however, only ultra violet rays between 0.40u and 0.22u are used. These rays are produced by the mercury vapor arc in great richness when it is operated at comparatively high temperatures obtained by higher voltages than are common to this arc, viz., about 70 volts for the 110-volt lamp and 170 volts for the 220-volt lamp. The needed ballast resistance for supporting such an arc reduces the line voltage to proper terminal voltages for the lamps.

To accommodate the temperatures and to offer little or no interference to the escape of the rays, fused rock crystals are used to make the quartz lamp. The mercury is hermetically sealed in the lamp after the vacuum is obtained; the seals being graduated from full quartz to glass in several steps, to permit maintenance of the seal and vacuum, by satisfying the two critical coefficients of expansion, i. e., those of the platinum wire connectors and of the quartz itself.



Vapor Electrical Apparatus Employing Metal Chamber.

The vertical cylindrical chamber forms the cathode and holds the mercury when the lamp is running, the anode being the tungsten button at the far end of the horizontal tube of the lamp proper.

To start the lamp, tilting is required to break the mercury bridge; this is done automatically or manually, according to the type of sterilizer. Immediately upon tilting, the arc is struck and the mercury is vaporized, and pressure is built up which pushes the mercury back into the vertical cylindrical chamber. While running, the mercury is continually vaporized and condensed.

The lamps are protected in starting by an automatic device which operates in series with the lamp;

---

*50 Broad St., New York.

at first current is passed through all of the ballast resistance provided until a certain amperage is reached, whereupon automatically a solenoid drops and cuts out resistance to the proper amount for correct running conditions. Should service be interrupted, this device automatically safeguards the lamp.

Automatic tilting of the lamp is effected in somewhat a similar manner. At the instant current is supplied to the lamp a magnet coil connected in series with the lamp is energized, and by this means the lamp is raised into its running position, thus striking the arc. All ballast is in series at the time of starting, but will gradually be partially cut out.

Lamp-starting current demands are about 100% over the running load; electrical equipment correlated with the sterilizers should be able to maintain this overload for 15 to 20 minutes, though actually the overload is drawn in an initial and a succeeding peak and both gradually reduce to running current load. This applies particularly to motor generator sets furnished to transform available electric service to lamp requirements. With either the 110-volt or 220-volt lamp, voltage regulation must be within 5% above or below the stated figure.

To transmit the ultra violet light to water for sterilizing the latter and to prevent heat exchange from the lamp to the water, a quartz protecting tube is used. Glass is unavailable, since it is practically impervious to ultra violet light. This quartz tube is inserted in the sterilizer and inside it is placed the lamp. The water to be sterilized is passed around the tube. The tube is made watertight by stuffing-boxes packed with rubber and protected by aluminum heat rings.

The problem of producing automatic apparatus for sterilizing water involves both sanitary as well as electrical and mechanical requirements. Since time is required to bring the lamp into running condition from a cold start, or of returning it to running condition from stoppage due to possible current interruption, etc., it is necessary that no water flow through the sterilizer during such periods. These conditions are easily satisfied by a solenoid valve in the water line and two simple relays, one a series, the other a shunt, in connection with the lamp circuit.

The series relay closes the line to the shunt relay at a certain current demand by the lamp; the shunt relay, then free to operate and in shunt with the lamp itself, closes the line to the solenoid valve when a certain voltage has been reached, which means proper running conditions have been obtained, whereupon the water line is opened up and water flows through the sterilizer. Either interruption of electric service, failure of lamp, or incorrect operation of the latter will close off the water line by de-energizing the solenoid valve via either one or both of these relays.

Tungsten Arc Lamp.

An enclosed tungsten arc lamp suitable as a source of ultra violet light, and designated the Quartz Pointolite Lamp, is described by *Morphy* and *Mullard* (J. Rontgen. Soc. 12, 70-4, 1916; Chem. Abs. 1917, 235). In the operation of this lamp a tungsten filament, which also forms the electrode, is heated by a shunt circuit which is closed temporarily when the lamp is switched on. The ionization of the gas brought about by the hot filament permits a current to pass across the gap to the tungsten globule which forms the other electrode, thus striking the arc, which can then be maintained indefinitely. When the lamp is run with a sufficiently high current the output of ultra violet light is of the same order as from the open tungsten arc and the objections of unsteady working and the production of white fumes of tungsten oxide are avoided.

Tungsten and Nickel Electrodes.

To weaken the spark obtained by a metallic arc, *Kowalski-Wirusz* (Fr. Pat. 468,215, Feb. 5, 1914) proposes electrodes of nickel, tungsten or their alloys, either alone or in combination with rare earths. By an appropriate choice of electric constants, and employing a wave length of less than 300u a great amplitude of current intensity is obtained. The ultra violet rays, produced on sparking, may be used for sterilizing liquids. The efficiency is increased by using different materials for the two electrodes and plunging them into the liquid to be treated. For the production of chemical reactions where the gases formed by electric action would be objectionable, a screen, such as quartz, may be interposed between the source of light and the material under treatment.

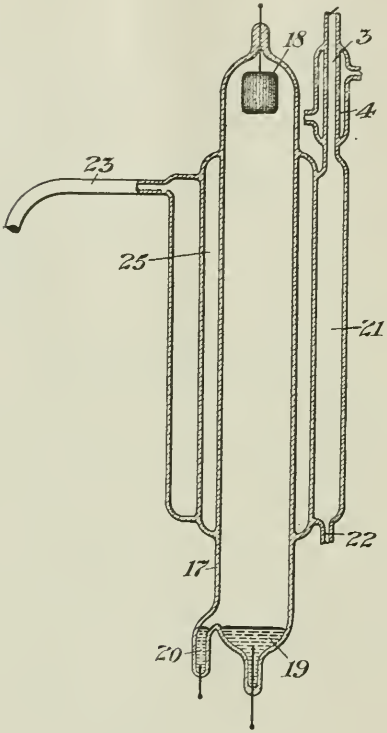
Apparatus for Chlorination.

Keyes (U. S. patent 1,237,652, August 21, 1917) describes an apparatus for the catalytic synthesis of organic substitution products especially for the production of chlorine or bromine derivatives of hydrocarbons. In the figure (p. 32), 17 is a tubular portion of a mercury vapor apparatus having a quartz container, an anode 18, a mercury cathode, 19, and a starting anode 20. This vapor apparatus is surrounded with a jacket, 21, having an inlet, 22, and an outlet, 23, a vent, 3, and a condenser 4. The tube 17 may be surrounded with a jacket, 25, which jacket may be exhausted. All the parts except the electrodes, may be made of quartz. This apparatus is adapted to continuous operation. In operation, halogen mixed with a hydrocarbon are fed at the inlet, 22, and pass up and around the tube 17, being acted upon as they pass by the radiations produced by the current and finally being delivered to the outlet 23. With the vacuum jacket around the tube, 17, the liquids passing through the jacket, 21, are protected from the heat produced by the lamp. Two other modifications of the apparatus are also shown.

Lamp for Treating Liquids or Gases.

In a process described by Ges. Quartz-Lampen

(British patent 13,624, Sept. 24, 1915; Chem. Abs. 1917, 412) liquid or gas is passed through a jacket formed by coaxial tubes and closely surrounding a mercury vapor lamp. The inner tube of the jacket is of silica or other material transparent to the active radiation; the outer tube may be of material which reflects the radiation. The lamp container and inner tube are conically ground to fit together near their lower ends, and if desired, near their upper ends also; in the latter case the narrow intermediate space may be exhausted. To reduce absorption by the mercury, the discharge is driven towards the container by electro-magnets which form a series resistance for the lamp and may be arranged in a helical row. As the discharge is thus given a helical form, the liquid or gas may be directed in a similar path by baffles or by a helical groove in the outer wall of the jacket.



Keyes Apparatus for Chlorination.

Ozonizing Apparatus.

Davis (U. S. Pat. 1,209,132, Dec. 19, 1916; Chem. Abs. 1917, 549) subjects air to violet and ultra violet rays and partially ozonizes it by exposing it between a thin silica plate supported on an iron plate, and a glass disk, having an overlying layer of carbon. The iron and carbon plates are connected to terminals of an electric circuit and air is drawn between the plates by a fan. Spacing blocks of insulating material separate the silica and glass plates. An alternating current is preferably used, as it is stated to cause the impurities in the air to separate and collect upon the surfaces of the plates.

Bovie (J. Biol. Chem. 20, 315-20, 1915) describes simple quartz mercury vapor lamps for biological and photochemical investigations. Directions are given for making lamps of various types in the laboratory, which are useful in experiments on the biological and chemical effects of ultra violet light.

Apparatus for Producing Very Short Wave Lengths

It is noted by Tian (Compt. rend. 156, 1063) in experiments on the effect of ultra violet light on water, that the endothermic combinations produced by rays of very short wave length (1900 Angstrom units) are often destroyed by the other ultra violet radiations. In making ozone or in other processes which use the very short waves it is necessary to avoid those rays which tend to restrict the reaction. When quartz lamps are used they must be operated at a low voltage as the total emission of ultra violet light increases greatly with the voltage while the energy of the rays shorter than 1900 varies much less. Tian describes a lamp made of a tube of transparent quartz down the center of which an insulated iron wire passes, thus making contact with a drop of mercury at the bottom, which forms the cathode. The anode is a small iron cylinder. Ordinarily direct current is used, but alternating current may be used if the anode is made double, i. e., two plates separated by a sheet of mica. The special advantage of this form of lamp besides operating at low voltage is that it is of convenient form to immerse in liquids.

Billon-Daguerre (French patent 419,117, Oct. 18, 1909) uses Geissler tubes constructed of silica and containing more or less rarefied gases for the production of hyper-ultra violet rays of short wave length. Several forms of lamp are described which may be provided with a vacuum jacket. When a liquid is to be sterilized it is passed in a thin layer over the surface of the lamp, or is conducted through tubes where it is subjected to the action of the rays emitted from the lamp.

Use of Resonance Transformer.

Kowalski (Compt. rend 158, 1337-9; Bull. Soc. Int. Elec. 4, 437-50) shows that the region of maximum radiated energy is displaced towards the longer wave lengths as the oscillatory current is increased. Increasing the amount of energy consumed in the spark, however, causes displacement toward the shorter wave lengths, but this displacement is dependent in a degree upon the nature of the electrodes. The intensity of the mean ultra violet ray, used in photochemical reactions and in sterilization, varies inversely with the frequency. A definite relation can be established between the number of sparks per second, capacity, and frequency of the primary current, if a resonance transformer is used, and thus it is possible to determine the most economical conditions for working the lamp.

Effect of Cooling.

Henri (Comptes, rend. 1911, 153, 426), during experiments on the ultra violet radiation from a mercury vapor lamp has shown that the radiation becomes more intense as the temperature of the luminous tube is allowed to rise. By cooling the tube with water, the radiation was found to be 14 times less powerful than with air, the same number of watts being consumed. The yield seems to depend on the fall of potential in the luminous tube. Quartz mercury vapor lamps have proved to be a very constant source of ultra violet rays and one in which the radiation is definite when the voltage, amperage and length of the tube are known.

Method of Cooling Lamps.

According to *Weigert*, (Z. physik. Chem., 1912, 80, 67) the quantitative study of photochemical gas reactions under the influence of ultra violet radiation is rendered difficult by the temperature effect produced when the lamp is in action. Attempts to avoid this by water cooling usually involve the passage of the radiation through a layer of water where it is largely absorbed. In the Weigert's apparatus, which is water cooled, the reaction takes place in a vessel outside the lamp itself, but the reaction vessel receives radiation which has only passed through such non-absorbing media as quartz and hydrogen.

Tubular Treating Apparatus.

In treating liquids with ultra violet light *Kowalski-Wierusz* (French patent 468,216. Feb. 5, 1914) sprays the liquids to be treated into a series of vertical tubes by means of compressed air or steam. These tubes are arranged about a lamp emitting ultra violet rays and have their lower ends connected with a collecting vessel. In another form of apparatus the liquid is sprayed directly into a chamber containing the lamp. Oil, or oil mixed with oxygen before being submitted to the action of the rays, may be treated in this manner to secure a bleaching effect.

Cadmium Vapor Arc Lamp.

Sand (Elec. Rev. West. Elec. 67, 654; Chem. News 112,151, 1915) describes a cadmium vapor arc lamp the use of which is recommended for polarimetric and other purposes, which is comparable in general principle with the mercury vapor lamp. The lamp is constructed of quartz glass. The cadmium is freed from oxide and dissolved gas by a process of filtration while at the pump. It is hindered from adhering to the glass by the presence of a small amount of a loose powder (zirconia) in the lamp. The metal is melted by external heating before starting, and maintains itself in the molten condition by the heat of the current. Once started, the lamp may be kept burning for an indefinite time.

Ray Filters.

Norsk Hydro-electrisk Kvaelstofaktieselskab (Norwegian patent 27,363, Oct. 23, 1916; Chem. Abs. 1917, 280), in a process for effecting chemical reactions between gases by means of ultra violet rays, use a ray filter for shading off ultra violet rays, so that only those wave lengths come into action which produce the desired reaction.

Light-Filter Used in Observations on Fluorescence and Phosphorescence.

A filter for ultra violet rays used by *Lehmann* (Physik. Zeits. 1910, 1039. Chem. Zent., 1911, 1, 55) consists of a vessel of Jena blue "uviol" glass filled with copper sulphate solution, and coated on the outside with a preparation of nitrosodimethylaniline and gelatine. A quartz lamp or an iron arc is used as the source of ultra violet rays and lenses of quartz of "U-V" crown glass for concentrating the rays. In describing the possible applications of such a light filter, it is pointed out that on exposure to the rays, chemically pure substances exhibit luminescence only faintly, whereas commercial products of second quality show a very strong luminescence. Different types of glass each exhibit characteristic fluorescence-colors. Many substances exhibit notable phosphorescence; rods of fused sodium hydroxide, for example, show a reddish-white effect in the cone of ultra violet rays, and a green color when rapidly moved away.

Detection of Metals.

Andrews (Gen. Elec. Review 1916, 317) describes an apparatus for the production of ultra violet rays for the detection of various metals. Andrews proposes the use of electrodes of iron, zinc, cadmium, magnesium, nickel, cobalt, etc., stating that some of these produce great intensity of ultra violet rays in certain regions of the spectrum but that for general work iron is more satisfactory because the length of the rays produced are more uniformly distributed throughout the entire range. Andrews states that when the wave lengths which are invisible to the eye fall upon certain substances, these substances are excited and show fluorescence, that is, reflecting the light in the visible spectrum. Some substances, such as barium sulphide continue to glow for some time after being excited, while others merely show the effect while the ultra violet light is shining upon them. Andrews proposes a method of determining whether the lens of ordinary spectacles or eyeglasses are of the proper material to protect the eyes by inserting the lens between the source of light and a metal which shows fluorescence. If the fluorescence continues the lens is not impervious to ultra violet rays. Various substances show different colors when exposed to ultra violet light, for example, calcite shows red; barium sulphide, orange; cadmium compounds, yellow; willemite, green; salts of salicylic acid, blue; some compounds of calcium, violet.

Ultra Violet Light Absorption by Glass.

The absorption of ultra violet light by various kinds of glass was investigated by *Ham*, *Fehr* and *Bitner*. (Penn. State College Report 1914, Part I, 158-62, published 1916) for the purpose of finding suitable protective glasses for the eyes. It is concluded that glass is opaque to wave lengths below the 302 line and therefore the rays which are generally conceded to be the extremely harmful are cut out. Until more data is obtained it is recommended that those glasses which do not absorb almost completely the 365 line should be rejected. The method of testing is given in detail.

Protection of the Eyes from Ultra Violet Rays.

The Seaman gold medal, which is annually awarded for progress in the promotion of hygiene, has been conferred upon the Julius King Optical Company, for research in overcoming the harmful effects of ultra violet and infra red rays of light in connection with arc-welding and other industrial processes at very high temperatures. (J. Ind. & Engr. Chem., 1917, 683.)

Any light source over 2000°F. is a distinct menace, and when a temperature of 6400° is reached, such as is encountered in electric carbon arc-welding, the volume of ultra violet radiation is so great as to impair vision permanently. Until an investigation was made about three years ago, practically 90 per cent. of all colored glass in goggles for industrial use was incorrect.

One of the first forms of eye protection from glare was the wearing of blue glasses in the manufacture of steel, particularly in the open-hearth process. Glare is made up of non-injurious rays of the spectrum, namely, green, yellow, orange and red rays. As a matter of fact, blue is stated to be one of the worst colors which could possibly be selected, as it allows ultra violet, violet, blue and also infra red rays to enter the eyes, cutting out only that part of the light which is essential to vision, but affording no protection from dangerous light.

A temperature of 2000° F. requires a lens but slightly tinted, while a temperature of 6400° requires a lens so dark that one can barely see the sun through it. The Julius King Optical Company has plotted all colors on a photometric scale, the standard adopted being a white cloud illuminated by the sun, which may be looked at indefinitely without eyestrain. A temperature of 2000° of molten iron through a slightly tinted glass has the same effect as if the wearer had nothing over the eyes, and was looking at a white cloud. The same photometric standard applies in looking at a temperature of 6400° through the darkest glass, the effect on the eye being the same.

The process of arc-welding requires protection not only for the eyes, but for the entire face and neck. Welders have experienced such intense eye strain and face burns after a few minutes' work, that all sorts of crude shields have been devised. The majority of these, however, were heavy and cumbersome, being made of metal and leather.

Since metal is a conductor of heat and electricity, the Julius King Optical Company have constructed a helmet of fiber, finished within and without in dead black so as to minimize the danger from reflected light. The top of the head is protected by a fireproof cap, to which the helmet is pivoted so that it may be turned back out of the range of vision when it becomes necessary for the wearer to inspect his work or to move about. The lenses mounted in this helmet are a combination of "Ark-weld" and "Akopos" glass, the former to reduce the intensity and the latter to eliminate the injurious rays of the arc light.

Illuminating Value of the Quartz Mercury Vapor Lamp.

Clewell (Electrical World, 1109, 1917), in a discussion of modern lamps and their application in the solution of lighting problems, considers the quartz mercury vapor lamp. He states that by virtue of the high candle power rating of these lamps as compared with other types, and for lighting large areas having the source of light on high poles such as for yard lighting, the quartz mercury arc lamp is very efficient; a glass globe used in connection with these lamps cuts off the ultra violet rays and thus provides a very efficient and safe source of light for these uses.

(To be continued in the December issue.)

Postal Savings Deposits Will Not Be Seized by the Government.

Postmaster Patten invites attention to the information contained in the following important notice which is of special interest to the public:

Some misapprehension seems to exist relative to the status under the trading-with-the-enemy act, of citizens or subjects of Germany or its allies resident in this country. Such persons are not included within the term "enemy or ally of enemy" as employed in the act. Deposits in the postal savings banks of the United States belonging to such persons are not liable to seizure by the Government, and will not, therefore, be taken into the possession of the alien property custodian or be interfered with in any way whatever.

(Official Bulletin, Washington, D. C., October 30, 1917.)

Order Department, P. O., New York, N. Y. November 2, 1917.

High Products Chemical Co.

With a capital of $500,000, the High Products Chemical Company has been incorporated at Newark, N. J., to manufacture chemicals and kindred products. The incorporators are Carl Dorgschlag, William Gerlach and H. C. Pfaff, Newark.

Walker Chemical Co.

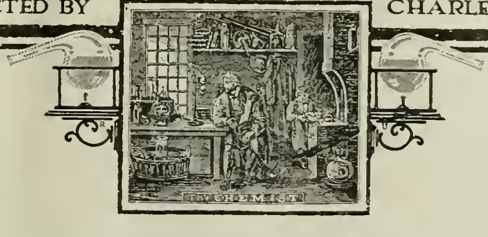
The Walker Chemical Company, Philadelphia, Pa., has been incorporated under the laws of that state to manufacture chemicals. The capital is $10,000 and the incorporators are F. R. Hansell, Philadelphia, and S. C. Seymour, Camden, N. J.

Hudson on Semet-Solvay Board of Directors.

Alfred W. Hudson, president of the First National Bank of Syracuse, N. Y., has been elected to the board of directors of the Semet-Solvay Company, that city, to succeed the late Frederick R. Hazard.

CHEMICAL INVESTIGATION
EFFICIENCY & CONTROL

CONDUCTED BY CHARLES B. DAVIS, F.C.S.



ALL classes of work covered by the following subjects will be done for readers of "The Chemical Engineer" through this department by Mr. Davis: Special research of every description; analysis and reproduction of any commercial product; prevention of waste and utilization of by-products on the most economical basis; valuation of raw materials; food analysis, and disputed points in regard to adulteration, labeling, and the enforcement of pure food laws; bacteriological and enzymatic examinations, including fermentation tests, pure yeast cultures, beverages of all kinds; development of chemical inventions and industrial processes; examinations and advice on special machinery.

Inquiries of a minor character will be answered on this page, while major matters involving personal investigations, analyses, etc., will, if desired, be treated confidentially through the mails. All questions, materials for analysis, or letters leading to the opening of negotiations for special work will receive prompt attention if addressed to

CHARLES B. DAVIS,
Care of "The Chemical Engineer," 118 East 28th Street,
New York City.

A. S. T.—I am sorry to have kept you waiting so long for an answer, but your question required considerable investigation and research and, as there were a number of letters ahead of yours, the delay was unavoidable. Nevertheless, it will appear in the next issue.

W. T. T.—If you will forward me samples of your porcelain, I will submit them to the following tests:

1. Resistance of glaze to chemical action.
2. Fusion point.
3. Chemical composition.
4. Translucency.
5. Effect of repeated heating and cooling.
6. Effect of sudden cooling.

As this type of work requires special care and considerable time, a small fee must be charged, depending on the number of samples, etc.

W. G. R.—As I have mentioned in these columns before, a paint containing more than one per cent of water will not dry readily. You had better ship me a sample from your stock so that I may determine the water content and also if the solvent is such as may cause trouble. For this class of test a small fee will be charged.

A. I. S.—The coke-oven benzol you mention is composed chiefly of toluene, benzene, paraffin, xylene and bisulphide of carbon, most of which will pass over at 171°C.

If you will send me these fractions I will determine the various constituents. Samples of about one pint should be forwarded.

Dr. F. S.—Brilliant Green, the anilin dye, is now being used extensively for wounds. Its chemical name is Tetraethyldi-fi-Aminotriphenylcarbidride Sulphate, zinc double chloride, or rarely oxalate. All are lustrous and brassy yellow in color, and soluble in alcohol and water.

The allied brands are:

Brilliant Green.
Malachite Green G.
Diamond Green G (B).
Emerald Green.
Fast Green.
Ethyl Green.
New Victoria Green.

These are usually employed for dyeing silk, wool, leather, etc., but have lately come into use in surgery, chiefly on account of the war.

I. W. C. Co.—A ductile filament can be produced by starting with a powdered refractory metal, sindering in atmosphere of hydrogen and vapor of tungsten halogen salt, at high temperature.

The tungsten salt will fill the minute spaces in the powdered metal, and a solid massed body obtained which can be worked into filaments with the present machinery you now have.

W. S. A.—The sample of dental porcelain you submitted for rational chemical analysis was found to have the following composition:

Feldspar	60.91
Clay	1.02
Flint	25.00
Quartz	4.50
Bone Ash	1.60
Sodium Carbonate	0.75
Calcium Carbonate	2.25
Potassium Carbonate	0.82
Borax	3.15
	100.00

Charles B. Davis.

Those whose inquiries to this department have not as yet received attention must bear in mind that unless replies by mail are specifically requested, communications can only be considered in the order of their receipt.—Editor.

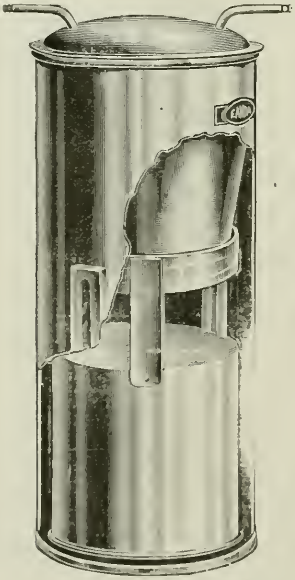
NEW APPARATUS

Conducted by F. W. S.

From month to month the newest forms of apparatus of interest to chemists and chemical engineers will be described and illustrated in this department. Information as to where various articles can be purchased may be obtained by addressing The Chemical Engineer, 118 East Twenty-eighth Street, New York City.

The Plaisance Extraction Apparatus.

Below is pictured a new form of extraction apparatus designed by Professor Plaisance of Iowa State University. It is intended for the extraction of larger quantities than are ordinarily used in the laboratory. As manufactured in the stock size, the inner vessel has a capacity of about two quarts and the outer vessel about two gallons. However, this apparatus can be made in any size desired. The stock apparatus is of heavy copper, but any other available metal can be used. The apparatus is particularly recommended for the extraction of herbs and flowers, general food work, asphalt and rubber extractions, etc.



Plaisance Extraction Apparatus.

New Plant for Linde Air Products.

The manufacture of oxygen and other air products in a new plant at Norfolk, Va., is contemplated by the Linde Air Products Company, New York City. The firm has already acquired a site at Norfolk for the erection of a plant for this purpose.

An Optical Pyrometer for Works Use

For the measurement of temperatures above 1400° F., only two methods have been found practicable for works service. One of these is based on the thermocouple, used either with the millivoltmeter or with the more accurate and reliable potentiometer. The other method is based on the laws of radiation and includes both the radiation pyrometer and the optical pyrometer, which utilizes only that radiant energy visible to the human eye.

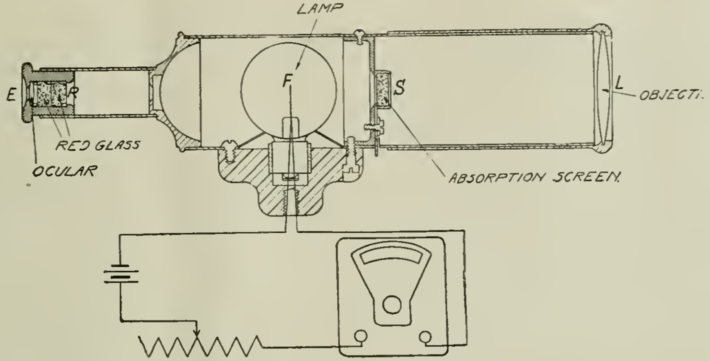
For many services the inexpensive and sturdy base-metal couple may be used for accurate measurements up to 2000° F., with entire satisfaction; the more fragile and expensive platinum couple may be used up to 2800° F., but the thermocouple, like thermometers in general, must assume the temperature of the hot object by convention, conduction, radiation, or all combined. This fact militates against its use for measuring the temperature of molten brass, iron and other metals, or for measuring temperatures in gas producers and other locations where the

The Leeds & Northrup Optical Pyrometer in Use.

thermocouple would be subjected to rough mechanical treatment or to contamination by vapors and gases, which would rapidly impair its accuracy. In many industries the temperatures used are far above the range of thermocouples.

Measurement by Light Radiation.

Measurements by radiation can be carried out at a distance, once the laws connecting temperature of radiating body and intensity of radiation have been determined, and the radiation receiving and measuring part need not be heated to the temperature of the radiating body, nor even anywhere near to that temperature. Pyrometers utilizing radiation are divided into two classes, those which measure as heat energy and the total radiation falling upon the receiving part of the instrument, and those, known as optical pyrometers, which are based upon the fact that the luminous radiation or light varies in a definite manner as the temperature of the hot body changes.



The greatest success has been attained by separating out one kind or wave length of radiation, usually that which excites the sensation of red, and comparing the intensity of this one-color light with the intensity of the light of the same color emitted by a standard source of light. The eye is very sensitive when comparing the brightness of two surfaces when one is superposed upon the other, and after having arranged to have light from the hot body and light from the standard of comparison viewed in this relation, they can be made equal, either by varying the amount of light received from the incandescent object, or by varying the intensity of the standard of comparison.

The latter method, that is, variation of the intensity of the standard of comparison, is preferred and used by the U. S. Bureau of Standards, also by the Reichsantalt, of Berlin, where its practical application has been brought to a high degree of perfection by Messrs. Holborn and Kurlbaum. The Leeds & Northrup Co., of Philadelphia, working under the fundamental Morse patents, has lately carried on a prolonged investigation and development of this type of optical pyrometer with a view to realizing a high degree of accuracy and reliability in a simple and portable device. The instrument, which is illustrated herewith, is suitable for measuring from dull red (about 1100°F.) up to the highest known temperature.

The manner in which the luminous radiation from the hot body is balanced against that from the standardized source will be understood by reference to the accompanying figure.

Description of Pyrometer.

L is a lens by which rays from the hot body at C are brought to a focus in the plane F, where there is located a tungsten lamp filament. By means of the eye piece E, the observer views the incandescent filament, which appears to lie upon the image, just as the cross hairs in a surveyor's telescope appear upon the distant object looked at. By means of a rheostat in a case slung about the neck, the case also containing a storage battery and a milliammeter, the current through the lamp is adjusted until the brightness of the filament is just equal to the brightness of the image produced by the lens, that is, so that the filament blends with, or becomes indistinguishable upon, the background formed by the hot object. The observer than notes the reading of the milliammeter, which may be provided either with a special scale to read in degrees of temperature, or the temperature corresponding to the current may be read from a calibration curve supplied with the instrument.

The adjustment is made with great accuracy and certainty, as the effect of radiation upon the eye varies some 20 times faster than does the temperature at 1300°F., and some 14 times faster at 3400°F., while as above stated, the eye is very keen in distinguishing differences in brightness between superposed objects.

At high temperatures the light emitted by both the hot body and the filament would become dazzling, and comparison would be difficult. For this reason a red glass is placed in the eye piece at R, which has the further advantage that light of only one color then reaches the eye and no difficulty is introduced by lack of color identity between the light emitted by the hot body and that emitted by the filament. The intensity of light radiation of any one color increases progressively in a definite manner as the temperature of the radiating body rises, and nothing is therefore lost by eliminating all other light from the comparison. As only brightness, not color, of light is matched, inability to distinguish colors, and color-blindness, do not interfere with the use of the instrument.

Brightness of Image Is Constant.

The brightness of the image of the hot body produced by the lens L is almost absolutely constant, irrespective of the distance from the hot body, although the size of the image varies with the distance. Since it is the brightness of the image and not the total radiation received through the lens that is measured, it is possible to measure the temperature of a small body or of a body at a distance equally as well as that of a large body or of one near at hand. It is not at all necessary that the hot body should fill the entire field of view of the instrument, as with total radiation pyrometers.

In observing bodies at very high temperatures, as 2,500° to 10,000° F., the light received through the lens would be too blinding for direct observation, even through the red glass of the eye piece, and the intensity of the image might also become greater than that at which it is practicable to burn the tungsten filament, so that a balance would become impossible. Some method for reducing the intensity of the light from the hot body, such as by varying the aperture through which the light is received or by placing a screen to intercept some of the light, is therefore necessary. A screen is used, placed between the lens and the image, so that it reduces the light from the hot body, but not that from the filament. With the reducing screen it is possible to make direct observations of the most brilliant light sources, as the electric arc or the surface of the sun.

Application of Wien's Law.

It is not feasible to calibrate the instrument at such high temperatures by direct comparison, since they are above all known melting points and the ranges of contact thermometers, but fortunately a relation has been found to exist between temperature and intensity of radiation of any one color or wave length of light. By making use of this relation, known as Wien's Law, and reducing the intensity of the image in a known ratio by means of the screen just referred to, it is possible to extend the scale of the instrument to the highest temperature. The scale thus obtained has been found to agree very closely with a scale of temperatures established by known facts about the relation between temperatures and total radiation. In other words, this form of optical pyrometer gives the same scale of temperature as do total energy pyrometers used with the precautions necessary to secure accuracy and precision in the measurement of total radiation.

Use of the Absorption Screen.

The screen used for cutting off part of the radiation from very hot bodies can be thrown into or out of the field of view by means of a milled disk projecting through an opening in the tube of the instrument. With the absorbing screen in use, a different milliammeter scale or calibration curve is required, but as the range of the instrument without the absorbing screen overlaps many hundred degrees with the range for the absorbing screen, the accuracy of the two scales can always be checked by observing a hot body whose temperature lies within this range.

The readings obtained with this instrument are always the same for the same temperature, if the body viewed is surrounded by other objects, such as the walls of a furnace at the same temperature. Also no correction is required in the case of so-called "black bodies," such as incandescent carbon, when viewed in the open. For iron and steel in the solid state, the corrections required for readings taken in the open are also negligible.

Objects having a metallic sheen, that is, a surface which reflects light freely, as molten metal or polished platinum, do not give the same readings when viewed in the open as when viewed in the furnace, or as a black body would give with this or any other radiation or optical pyrometer. The readings, however, are always consistent for the same material under the same conditions.

Preparation of the Lamp.

The instrument can be calibrated by sighting it upon bodies whose temperatures are known, either by means of a thermocouple pyrometer, or by the melting or freezing of various substances. The constancy or reliability depends upon the constancy of the lamp, that is, its ability always to shine with the same intensity when receiving the same current. This matter has been investigated exhaustively by the U. S. Bureau of Standards and by the Nela Park Laboratory of the National Electric Light Association, also in the laboratory of the Leeds & Northrup Co., and it has been found that after a tungsten filament is thoroughly aged, that is, burned for some time at a temperature higher than that to which it will be subjected in service, no sensible variation thereafter occurs. The instrument is so designed that one lamp can quickly be replaced by another, and by keeping two lamps, their correctness can always be insured by checking one against the other.

The instrument itself is handy and portable, weighing only a few ounces, and can be sighted as easily as an opera glass. The case, containing the battery, rheostat and milliammeter, is designed to be slung about the neck, and weighs about 10 lbs.

FOREIGN TRADE OPPORTUNITIES

These Opportunities for Foreign Business Relations Are Made Public by the Bureau of Foreign and Domestic Commerce, of the Department of Commerce, Washington, D. C. Names, Addresses and Details May Be Obtained from the Bureau or Any of Its Branches. Refer to the Number of Each Opportunity and Place Inquiries for More Than One on Separate Sheets.

Aniline Colors.

25353.—An agency is desired by a man in Argentina for the sale of aniline colors. Correspondence may be in English. References.

Refractory Materials.

25428.—An Italian gas company wants to buy large quantities of refractory material and articles connected with repairs in this industry. Correspondence may be in English. References.

Sulphur and Copper Sulphate.

25285.—A man in France wishes to buy sugar, dried vegetables, sulphur, sulphate of copper, lard and bacon. He also desires to entertain an agency proposition for the sale of these goods. Correspondence should be in French. References.

Calcium Carbide and Gas Generators.

25505.—A firm of India desires to be placed in communication with American manufacturers and exporters of electrical accessories, wire and cables, high-pressure kerosene-oil lamps, gas generators, carbide of calcium, petroleum, all kinds of stoves, pocket lamps, novelties, etc. References.

Chemicals.

25408.—The agency for hides, leather, belting, cocoa, coffee beans, sugar, iron, steel, copper and chemicals is desired by a Norwegian importer. Correspondence may be in either Norwegian or English.

Chemicals, Magnesium Chloride, Zinc Chloride.

25527.—A company in India wishes to be placed in communication with American manufacturers and exporters of piece goods, machinery, gin stores, hardware, dyes, colors, belting, grease, oils, lanterns, lamps, electrical goods, drugs, chemicals, patent medicines and drugs, wire nails, rosin, alum, rubber tubes, rubber sheets, asbestos packing and sheets, bobbins, bolts, nuts, hose pipes, rubber hose wire protected, cotton ropes, yarns, magnesium, chloride, zinc chloride, farina, files, tools, shovels, canned goods, wire netting, long cloth, drill, mosquito netting, flannel, etc., with a view to securing an agency for the sale of these goods. References.

Kerosene, Benzine, Benzol.

25471.—An agency is desired by a commission merchant in Spain for the sale of kerosene, lubricating oils, benzine, benzol and animal oils, including whale oil. Correspondence should be in Spanish. References.

Chemical Laboratory Outfit.

25351.—A foreign Government desires to purchase a chemical laboratory outfit to be used in connection with public instruction in chemistry or physics, and for analyzing food, drugs and other products. Quotations should be made f. o. b. New York or San Francisco. Goods should be very securely packed. Full information should be submitted. Correspondence should be in Spanish. References.

Dyes and Chemicals.

25529.—A company in India desires to secure an agency for the sale of cotton, woolen and mercerized piece goods, yarn, metal, hardware, glass and enamelware dyes, chemicals, paper, stationery and general sundries. Payment will be made against documents at 30 or 60 days' sight, if documents of acceptance is not practicable. References.

Chemical and Pharmaceutical Supplies.

25503.—An agency is desired by a commission merchant in Spain for the sale of patent medicines, remedies for animals and chemical and pharmaceutical supplies. Correspondence should be in Spanish. References.

Gasoline, Oils, Drugs and Chemicals.

25523.—A commission and shipping house in the United States, acting as agent for several foreign firms, desires to receive quotations from American manufacturers and exporters of petroleum, gasoline, asphalt, lumber, automobiles, cement, galvanized-iron sheets, iron bars for cement construction, agricultural implements, forage presses, wrought-iron pipes, textiles, provisions, flour, boots and shoes for women, drugs and chemicals, hardware, electrical supplies, paper, office supplies, men's furnishings, rope and twine, matches, lumber, cement machinery, lubricating oils, all kinds of leather and shoemakers' supplies and paint. Catalogues and samples should be submitted wherever possible. References.

DISTILLATES

News Notes of Chemical and Allied Industries

New Fertilizer Plant.

Swift & Company, Chicago, Ill., will expend $500,000 on the construction of a new fertilizer plant at Hammond.

Dr. Stevenson a Captain.

Dr. Reston Stevenson, assistant professor of physical chemistry in the College of the City of New York, has been commissioned a captain in the Sanitary Corps, U. S. A.

Addition to Chemical Plant.

The American Agricultural Chemical Company, Boston, Mass., is working on the construction of a one-story addition to its Portsmouth, N. H., chemical plant.

Newton Now With Falkenberg & Laucks.

Announcement has been made that Harry W. Newton has joined the staff of Falkenberg & Laucks, chemists and metallurgists, Seattle, Washington.

Penn Chemical Co. Adds to Plant.

The Penn Chemical Company, Philadelphia, Pa., has begun work on the construction of a one-story addition to its plant. The improvements will cost $25,000, the size of the addition being 25x45 feet.

Agricultural Chemical Co.

With a capital of $10,000, the Agricultural Chemical Company, Memphis, Tenn., has been incorporated under the laws of that state to manufacture chemicals and kindred products by Henry L. Sanders, F. E. Brown, J. B. Kelly, Memphis, and others.

Dr. McKee to Instruct Columbia Post-Graduates.

Dr. Ralph H. McKee has been appointed to take charge of the graduate work in industrial organic chemistry (Department of Chemical Engineering), Columbia University. Dr. McKee was for seven years head of the Department of Chemistry, University of Maine, where he accomplished the creation of the department for the making of pulp and paper, the first of its kind to be established in any college in the country.

Singer-Perlstein Company.

Philip A. Singer and Harris Perlstein have together formed the Singer Perlstein Company, chemical and industrial engineers. Both men were formerly of the Industrial Chemical Institute of Milwaukee. Mr. Singer is chiefly known for his research work in connection with the recovery of ethyl alcohol from wood paste, and Mr Perlstein has been associated with him in a number of recent enterprises. The offices of the new firm are in the Railway Exchange, Milwaukee.

Butterworth-Judson Adds to Plant.

At a cost of $10,000 the Butterworth-Judson Company, Newark, N. J., manufacturers of chemicals, will erect a one-story addition to the plant on Avenue R.

California Firm to Build New Plant.

The Butters Syndicate, Martinez, Cal., has acquired the plant of the Peyton Chemical Company and is completing the construction of a new plant for the manufacture of chemicals.

Motion Picture Films.

Motion picture films will be manufactured by the recently incorporated Betzwood Film Company, Philadelphia, Pa. The incorporators are F. R. Hansell, Philadelphia; J. V. Pimm and S. C. Seymour, Camden, N. J.

$1,500,000 Silica Corporation.

The Commonwealth Silica Company, Chicago, Ill., has been incorporated with a capital of $1,500,000 to mine for silica, lime and other substances. The incorporators are P. Zak, L. L. and B. F. Cowan, Chicago.

Nitro-Phospho Corporation.

To manufacture chemicals and their by-products, the Nitro-Phospho Corporation of New York has been incorporated at Newark, N. J., with a capital of $125,000. George R. Swain, C. Jacobs and J. I. Sipp, Newark, are the incorporators.

$2,500,000 Chemical Corporation.

The Natural Chemical Products Corporation has been incorporated under the laws of New York with a capital of $2,500,000 to manufacture chemicals and chemical products. The incorporators are S. B. Howard, L. H. Gunther and Joseph Curtin, New York.

N. J. Chemical Works Incorporated.

At Belleville, N. J., the Lloyd Chemical Works, Inc., has been incorporated to manufacture chemicals, dyes and allied products. The capital is $20,000 and the incorporators are M. and A. Vandeweghe and Ellis Lloyd, Belleville.

Lamie Chemical Company.

The recently incorporated Lamie Chemical Company, Huntington, W. Va., will undertake the manufacture of chemicals and allied products. The capital of the company is $50,000, and the incorporators are R. D. Lamie, Huntington; A. T. Roberts, Marquette, Mich.; H. W. Shelton, Negaunee, Mich.; John Garvin, Ontonagon, Mich., and Dan H. Ball, Marquette, Mich.

AMERICAN DYE MANUFACTURERS TO MEET IN NEW YORK

Not Since Great Britain Upheld Her Title of "Mistress of the Seas" and Proclaimed the Ocean Lanes "Verboten" to German Trading and Merchant Ships, Has the American Dye Industry Received So Powerful a Single Stimulus as the Approaching Conference of Color Makers Is Expected to Produce. Details of the Prospective Event, Together with Some of the Looked-for Benefits, Are Given in the Article Below.

American industrial history will be made at the meeting of dyestuff manufacturers and merchants to be held Tuesday and (if necessary) Wednesday, January 22 and 23, in Rumford Hall, The Chemists' Club Building, 50 East 41st street, New York. In fact, it is not too much to say that the prospective gathering gives every indication of becoming an event which those connected with the color industry will "date time from."

Although he persistently refuses to admit that his role has been anything more than that of a mere secretary, the man chiefly responsible for definite action leading to the coming conference is Mr. G. Gardner McKerrow, of New York. Be that as it may, it was he who many months ago saw clearly the benefits to be derived from a free interchange of ideas between those actively engaged in the manufacture of American dyestuffs; it was he who publicly called attention, through the press and from the platform, to the desirability of such a move; it was he who early interested and enlisted the sympathies of many important factors in the industry, and, when what was deemed the opportune moment had arrived, it was he whom they requested to sound the trade at large as to their feelings regarding a meeting.

Purpose of the Meeting.

The primary object of the gathering, at which some 200 color firms have already signified their intention of being represented, will be the creation of an organization which will enable the American manufacturers to complete their intrenchments against foreign competition, and to so coordinate the industry that when the present great military struggle is over, and the inevitable commercial struggle has begun, they shall not be deprived piecemeal of the fruits of the magnificent effort which they have made to create an independent American dye industry.

Just how it is proposed to accomplish this result, and the necessity for a general meeting in order to bring it about, is best indicated in the two letters sent out to the trade by Mr. McKerrow. The first of these follows:

"I have been requested by a number of gentlemen interested in the manufacture of American dyestuffs, to take the initial step looking to the convening of a Conference at which the question of the standardization of American colors can be discussed.

"I feel that there are others in the industry who have been identified with it for so much longer than I have that some one of these could more properly take this preliminary step, but in order to bring the matter to an issue and to give the industry as a whole a chance to meet and discuss this important and vital question I have decided to act upon the requests that have been made.

"May I suggest that a meeting be held, preferably in New York, as being the most available centre for all interests, during the week of January 21st, 1918?

"I should be pleased to hear from you as to whether this is in accordance with your ideas, and if so, whether this time will be as suitable to you as any other. Upon hearing from all those interested, or as many of them as care to reply, definite steps will be taken to organize this meeting."

Color Men Enthusiastic.

This letter brought forth an exceedingly gratifying response from a large number of concerns, which were quick to grasp the possibilities and viewed the project with notable optimism. So readily did the recipients take to the idea that Mr. McKerrow proceeded with arrangements, and shortly afterward the following letter, explaining further the object of the meeting, was sent out:

"Arrangements have been definitely made to hold the conference for the consideration of the best means for standardizing American dyestuffs, at which you have kindly agreed to be represented, on January 22nd, and if necessary, January 23d next, in Rumford Hall, The Chemists' Club, 50 East 41st street, New York City

"It is hoped that at this conference, at which about two hundred of the leading manufacturers of and dealers in intermediates and dyestuffs have expressed their intention of being present, a consolidation of the new industry may be effected, resulting in the formation of a National trade association, which shall have the interests of the industry permanently in its care, and which shall be representative of the dyestuff trade as a whole.

"No preliminary organization has been attempted and the ultimate developments will be entirely in the hands of those present at the conference. It is hoped, however, that gentlemen present will be prepared to make suggestions; to discuss questions affecting the industry, such as the tariff, arbitration of disputes, etc., as well as the question of the standardization of colors, and that a full and free interchange of ideas looking to the permanent intrenching of the industry may be obtained.

"A note of the final arrangements will be mailed to you about January 15th."

Some of the Expected Benefits.

The movement has been initiated for the purpose of effecting some authoritative method of standardizing American colors, and it is hoped that the conference will result in the formation of such an association representing the new dyestuff industry and which will be effective in protecting the interests of this industry, not only as regards standardization, but questions of arbitration, tariff, protection of contracts, etc.

If the plan is properly worked out, with all its ramifications, it will most certainly sound the commercial death-knell of the dishonest dye manufacturer and the unscrupuious broker. These two types of individual have done quite as much as any German propagandist in the way of discrediting the American dye industry in the eyes of the general public. But the activities of such undesirable citizens can be effectually eliminated, for, as Mr. McKerrow declares, "short of police or military force, which, of course, would hardly be available for this purpose, the best way to make a man live up to an ideal is to make it worth his while to do so," and this is one of the things which it is proposed to accomplish.

How Dye Standards May Be Regulated.

The initial idea regarding standardization is designed to overcome the difficulty under which the new industry is now working, in that every maker, if he has any standard at all, has his own, and this bears no relation either as regards the tinctorial value of the colors offered or the price, to the products of other manufacturers. The need of definite trade standards against which all colors may be tested as they are produced is not only urgently needed by the dyestuff manufacturing industry itself, but by the consumers in the color using industries, and is further also urgently required by the Government in its consideration of questions of tariff as bearing upon the dyestuff industry.

Government Will Be Represented.

The Government is to have representatives present at the conference, and these officials will undoubtedly give expression to the desires of the Government in this regard.

It is also hoped that the conference may result in the establishing of a board of arbitration, which will necessarily operate in parallel lines with the question of standardization in that the great majority of disputes which arise are as to whether deliveries have been equal to samples submitted. This difficulty has already been productive of an enormous number of lawsuits which entail endless delay and expense and which could properly be quickly and finally adjudicated by a mutual reference of the difficulties to an impartial board of arbitration supported by the authority of the trade organization and passing upon the merits of the case through the laboratory which will be established by the organization.

H. Gardner McKerrow.

"Let's Go!"

As one of the organs representing the industry, the CHEMICAL ENGINEER believes that it would be difficult to exaggerate the importance of this meeting, not only to the industry as a whole, but to the individual members of the National Association which it is to be hoped will result. And because of its earnest desire to render any service possible to those engaged in advancing the interests of the American dye industry, this publication further desires to emphasize its belief that the proposed conference will be highly beneficial in its results, to congratulate those who have decided to be represented, and to urge upon all others a further and careful consideration of the project.

Any individual or firm desiring additional information can obtain it by addressing Mr. McKerrow, in care of E. F. Drew & Company, Inc., 50 Broad street, New York City.

Some of the Elect.

Below follows a list of the firms which, up to the time when this issue went to press, had signified their intention of being represented at the conference:

A & B Export & Import Corp., 78 Wall Street, N. Y.
Ackerman Co., Inc., H. R., New York.
Agawam Chemical Works, Providence, R. I.
Althouse Chemical Co., Reading, Pa.
American Color & Manufacturing Co., Passaic, N. J.
Atlantic Dyestuff Co., Boston.
Atteaux & Co., F. E., Boston.
Ault & Wiborg Co., Cincinnati, Ohio.
Bayer Co., Inc., 117 Hudson street, New York.
Barrett & Co., M. L., Chicago, Ill.
Bick & Undy, Philadelphia, Pa.
Binney & Smith Co., New York.
Bird & Co., J. A. & W., Boston.
Bloede Co., Victor G., Baltimore.
Bosson & Lane, Atlantic, Mass.
Boston Dyewood & Color Co., 136 Federal St., Boston.
Bothamley & Co., 309 Broadway, New York.
Bowring & Co., 17 Battery Place, New York.
Cabot, Inc., Samuel, Boston.
Cambria Steel Co., Philadelphia, Pa.
Century Color Corp., 182 Front street, New York.
Chemical Co. of America, New York.
Commonwealth Color & Chemical Co., Brooklyn, N. Y.
Commonwealth Color & Chemical Co., Philadelphia.
Cosmic Aniline Works, Inc., New York.
Cronkhite Co., Boston.
Cullin, A. R., 104 S. Adams avenue, Margate, N. J.
Dana & Company, Inc., 111 Broadway, New York.
Delta Chemical Co., Inc., 11 Warren street, New York.
Dicks, David & Broadfoot, Inc., 302 Broadway, N. Y.
Dow Chemical Co., Midland, Mich.
Dunker & Perkins, Boston.
Dye Products & Chemical Co., Inc., New York.
Federal Dyestuffs & Chemical Corp., New York.
Fieldhouse, W. H., 176 Federal street, Boston.
Fine Colors Co., Paterson, N. J.
Fisher Chemical Co., 170 Summer street, Boston.
Ford Co., J. B., Wyandotte, Mich.
Fortner Co., L. B., 36 Strawberry street, Philadelphia
Fuerst Bros. & Co., New York.
Georgia Ochre Co., 165 Broadway, New York.
Gessler, Dudley D., Philadelphia.
Hadjopoulos & Sperco, Inc., 29 Broadway, New York.
Hartley, Frank, 146 Summer street, Boston.
Haight & Co., Samuel, 66 Batterymarch street, Boston.
Hellenic Chemical & Color Co., Inc., New York.
Heller & Co., B., Calumet ave., & 40th St., Chicago, Ill.
Heller & Merz Co., H. A., Newark, N. J.
Herman & Herman, Inc, New York.
Hine Bros., 80 Maiden Lane, New York.
Holland Aniline Co., Holland, Mich.
Holliday-Kemp Co., New York.
Hord Color Products Co., Sandusky, Ohio.
Huisking, Chas. L., New York.
Imex Corp., 25 Beaver street, New York.
Imperial Car Cleaner Co., 115 Chestnut St., Newark, N. J.
Innis, Speiden & Co., New York.
Iridescent Dyestuff Color Co., 251 Bush St., Brooklyn.
Jacksonville Chemical Mfg. Co., Jacksonville, Florida.
Jaeck Co., Louis, New York.
Jennings & Co., 93 Broad street, New York.
Jorgensen Co., Chas. A., 55 Franklin street, New York.
Katzenbach & Bullock Co., New York.
Kley, E., 40 Pine street, New York.
Klipstein & Sons Co., E. C., 644 Greenwich St., N. Y.
Kretschmar, A. W., 396 Broadway, New York.
Kuttroff, Pickhardt & Co., Inc., 128 Duane St., N. Y.
Lewis, John D., Providence, R. I.
Linburg, J. F., 101 Beekman street, New York.
Lyon, Julian W., 101 Beekman street, New York.
MacAndrews & Forbes Co., New York.
MacEvoy, Thos. J., 1126 Ontario street, Philadelphia.
Madero Bros., Inc., New York.
Manhattan Color and Chemical Co., New York.
Manhattan Trading Corp., 2 Rector street, New York.
Marden, Orth & Hastings Corp., New York.
Martin Co., The L., New York.
May & Co., Inc., Frank L., New York.
Middlesex Aniline Co., Inc., New York.
Monroe Color and Chemical Co., Quincy, Ill.
Monsanto Chemical Works, St. Louis, Mo.
Morrill, George H., Norwood, Mass.
Morris Co., F. Ellis, Drexel Bldg., Philadelphia.
Mount Union Tanning & Extracts Co., Mount Union, Pa.
National Aniline and Chemical Co., Inc., New York.
Newport Chemical Works, Inc., New York.
Oakes Mfg. Co., Long Island City, N. Y.
Obex Co., Marietta, Ohio.
Organic Products Corp., Schenectady, N. Y.
Osborn Co., C. J., 132 Nassau street, New York.
Parsell & Co., C. C., Chicago, Ill.
Peerless Color Co., Bound Brook, N. J.
Ph. Van Ommeren Corp., 42 Broadway, New York.
Read Holliday & Sons., Ltd., New York.
Reliance Aniline & Chemical Works, 100 Broadway, New York.
Rutherford & Co., J. G., 505 Broome street, New York
Seydel Manufacturing Co., Jersey City, N. J.
Sherman & Mason, 211 N. Front street, Philadelphia
Sherwin-Williams Co., Cleveland, O.
Sloan & Russell, 132 Nassau street, New York.
Stanley Aniline Chemical Works, Lock Haven, Pa
Tower Chemical Co., Inc., 253 Broadway, New York.
U. S. Dye Extracts Co., Inc., 801 Vernon avenue, Long Island City, N. Y.
United Supply Co., 826 Lafayette Bldg., Philadelphia
Waldo, E. M. & F., New York.
Western Aniline Products Co., Chicago, Ill.
White, Inc., John J., 149 Broadway, New York.
Williamsburg Chemical Co., Inc., Brooklyn, N. Y.
Wood, Inc., J. Early, 21 Platt street, New York.
Young Co., Frank L., Boston.

COAL-TAR CHEMISTRY SECTION

THE CHEMICAL ENGINEER

Devoted to the Interests of All Producers and Consumers of Coal-Tar Derivatives

Crudes, Intermediates. Artificial and Natural Colors.
Synthetic Medicinals, Flavors and Perfumes. Explosives,
Photographic Developers.

Edited by
THOMAS H. NORTON, Ph. D., Sc. D.

BOARD OF ASSOCIATE EDITORS.

B. R. Armour, American Aniline Products, Inc., New York.

George H. Bruce, LL.B., Keystone Fibre Products Co., Inc., New York.

Edward S. Chapin, Consulting Chemist, Boston, Mass.

B. Flurscheim, Ph.D., Aetna Explosives Company, New York.

John C. Hebden, A.B., Chemical Engineer, Providence, Rhode Island.

C. W. Hill, President of the C. W. Hill Co., Los Angeles.

H. Gardner McKerrow, of E. F. Drew & Co., Inc., New York.

Louis A. Olney, M.S., Professor of Chemistry, Lowell Textile School, Lowell, Mass.

Arthur Roberts, President of the American Coal and By-Products Coke Co., Chicago.

The Wrecking of Halifax by Trinitro-Toluene.

In none of the battles of the great war have high explosives caused such loss of life and such destruction of the results of human effort as happened in the terrible disaster which visited the city of Halifax on December 7. Through an accidental collision fire was started on a steamer laden with trinitro-toluene, making a brief stop in the harbor on its way to France. The quickly following explosion, brought about a loss of life going into the thousands, with greater numbers of seriously injured, while over 25,000 persons were suddenly rendered homeless. The destruction was so sudden, so widespread, that the disaster will rank historically with such earthquakes as those of Lisbon, San Francisco or Messina, or with the tragedies following great tidal waves or floods.

The material loss exceeds $25,000,000. Needless to say, the sympathies of the entire continent have gone out to the unhappy Nova Scotian city, and relief has streamed from every quarter.

There is a warning to us to be more closely upon our guard, in connection with the movements of all vessels transporting high explosives. It would appear that the ill-fated steamer in question carried also a large consignment of benzene as a deck cargo. This latter was first ignited and the impossibility of extinguishing this conflagration led to the fatal explosion.

Rigid regulations with regard to the character of freight carried upon a vessel conveying explosives should be established. Equally rigid regulations should control every movement of such a vessel when in or near a port.

Nowhere are such protective measures more needed than at the port of New York. The effect upon the skyscrapers of the city of an explosion of T.N.T., even at a distance of several miles, can easily be imagined.

Thus far there have been numerous serious and costly explosions in the factories where high explosives are manufactured. The tragedy at Halifax is the first to occur in connection with the transportation by water of the deadly material.

A Census of Coal Tar Products.

One of the first duties of the United States Tariff Commission is to provide for an exhaustive census of coal-tar products.

In the revenue act of September 8, 1916, special provisions were made to give additional tariff protection to coal-tar products. Coal-tar crudes continued on the free list. Coal-tar intermediates, however, are subject to an import duty of 15 per cent. *ad valorem,* plus a specific duty of 2½ cents per pound. Coal-tar colors, medicinals, flavors, perfumes, photographic developers, etc., pay an import duty of 30 per cent. *ad valorem.* In addition there is a specific duty of 5 cents per pound on all colors except anthracene dyes, indigo and the indigoids. At the expiration of 5 years (in 1921) these specific duties are to be diminished by 20 per cent. each year and disappear entirely in 1926. If, however, in 1921, it shall not be evident that the country is producing at least 60 per cent. of its consumption of the articles in question, then the specific duties shall be abolished at once.

It becomes the duty of the Tariff Commission to secure the needed statistical information for the purpose of deciding the extent of the national production in 1921, and its relation to the entire consumption. The Commission will naturally have the assistance of the Treasury Department in order to establish the amount of foreign importation four years hence, although in this connection uncertainties may arise as to just how much of the importation in a given fiscal year enters actually into consumption. This difficulty may be increased if it happens that 1921 arrives at a period when international exchanges are resumed and stocks generally are being renewed.

The Commission must depend upon its own efforts to establish the amount of the domestic production. It has wisely decided that it must promptly begin its apprenticeship. Accordingly it will make a preliminary enumeration in 1918, enabling it to get into touch with the entire coal-tar chemical industry. These relations will be maintained and presumably the Commission will be able in 1921 to secure promptly and accurately all neded data.

The Commission is undertaking a general survey of our chemical industries, and will present later to Congress important suggestions in connection with desirable changes in classification and rate schedules.

Especially in connection with coal-tar chemicals is there an ample field for improvement. It is still a puzzle to all chemists why synthetic medicinals, flavors, perfumes, etc., as well as anthracene colors, indigo and indigoids, should be excepted from the provisions of the specific duty of 5 cents per pound. It is impossible to present any logical reason why artificial indigo should not have the same protection as Methylene Blue or Victoria Blue. The word "indigoids" is, furthermore ambiguous and likely to lead to litigation. It is, also, not clear whether explosives are to be included under the classification of finished coal-tar products. All of these uncertainties should be promptly cleared up by clean-cut, accurate, logical legislation.

The Commission is issuing a circular letter of inquiry to all firms engaged in the manufacture of coal-tar chemical products, which will enable it to secure exact information as to the extent of the industry at present, and the amounts of the different chemicals now produced.

The ground work for this has already been laid by the extensive studies in this field carried on by the Bureau of Foreign and Domestic Commerce of the Department of Commerce.

A New Use for Naphthalene.

Under the stimulus of an increasing lack of many chemical products, hitherto regarded as essentials, German inventive genius is actively at work devising numerous substitutes. One of the latest results is to transform naphthalene into an oil which can be used for illuminating purposes, very much as petroleum. The reaction is effected by heat, under pressure, in the presence of aluminum chloride. Details on the operation are lacking. It may possibly open up a general method for the more abundant utilization of naphthalene than has hitherto been the case.

The Outlook in the United States for Technical Synthetic Chemistry.

There is a rapidly growing conviction that this country will become absolutely independent of foreign sources for its synthetic drugs and dyes, if there is the proper cooperation between governmental action, industrial enterprise and our institutions of higher scientific training. We can not attain and maintain such a position unless our facilities for research are brought up to the proper standard and a numerous corps of our younger chemists are attracted to the field of organic investigation. That this latter condition of success is well assured would appear to be the case as we analyse the current output of valuable memoirs issuing from American chemical laboratories, and devoted to problems in organic synthetic chemistry. Not a few American universities are becoming active centers of organic research and contributing results fully comparable in extent, as well as in technical and scientific value, to those of many German institutions.

Analogous conditions exist in several of the more powerful companies devoted to the manufacture of chemical products. During the past few years the scientific staffs of these organizations have been notably increased and the field of research broadened.

The general topic was admirably treated by Professor Julius Steiglitz in his address, as President of the American Chemical Society, at its September meeting in Boston. From this address the following pertinent passages are quoted:

"Much more than a question of coloring materials is concerned in a conscious policy to have our dye industries established on a permanent basis. It has often been emphasized that the manufacture of dyes is so closely related to the preparation of explosives that a flourishing dye industry in times of peace means ample facilities for explosives in times of war. No American would care to contemplate what our position would be in the matter of large scale production of explosives if we had become engaged in a struggle with a first-class power without the benefit of the great expansion in our dye and explosives factories which our commerce with England and France brought about after 1914! When peace comes, let no American forget this lesson! One way of insuring ourselves against a lack of facilities for a sudden expansion in the production of explosives is to keep capital invested in dye factories.

"Independence in the preparation of medicinal remedies, especially also of the finer modern products which we call synthetic drugs, should be as conscious an aim of the United States as independence in the manufacture of dyes. It is worth noting that the two aims support each other, for nearly all of the basic products needed for the large-scale preparation of synthetic remedies are either prepared in aniline dye factories, as intermediate steps toward dyes or are so closely related to such compounds that it would be a mere detail to include these products in the normal output of a dye factory. As an instance pointing in this direction, recent correspondence with a prominent American firm, which has invented and is manufacturing what promises to be a valuable substitute for cocaine in producing local anesthesia, brought out the fact that the chief difficulty in the way of production of the drug on the large scale which the situation demands, lies in the securing of sufficient quantities of the chemicals diethylaniline and cinnamic acid. Now, the former could and should be manufactured in dye factories with the greatest of ease, side by side with dimethyaniline, which is a common intermediate in the manufacture of many dyes, and cinnamic acid could be prepared from benzaldehyde, another intermediate. Furthermore, large research departments in well-organized dye factories will be centers of research in applied organic chemistry and practically all of our valuable synthetic drugs are such organic compounds. Indeed, it will be a matter of time only—and I should like to see that time shortened as much as possible—when some of our best-equipped and most progressive dye factories will turn to the problem of these remedies as a question of the economic utilization of their equipment. That has been the history abroad and it will be the same here. In fact, together with our long-established great pharmaceutical houses, they should find even richer, unexploited fields of effort in the problems of synthetic drugs than in those of dyes. Without question the average man spends on necessary drugs for his family at least a thousandfold the value of the dyes in the wardrobes of his whole family—the ladies, of course, included. The twitchings of rheumatism or gout, sleepless nights or a cantankerous cold are most urgent and persuasive drawers on a family purse. My professional friends know well how the modern dye industry has been built up on an accurate scientific knowledge of the connection between color and what we call the structure of the molecules, those minute worlds on the knowledge of which our power to reconstruct matter rests. We know, too, that the dye industry has reached, or almost reached, its full maturity and capacity. But we are only on the threshold of exactly the same kind of development in the discovery of improved remedies for curing human ills because the connection between the structure of our molecular worlds and their medicinal effect is just beginning to be systematically elaborated. Great industrial establishments founded on organic chemistry, like the dye manufacturing and the great pharmaceutical houses, collaborating with research laboratories in universities and in medical institutions, would hold out to this country the promise of a share in realizing a duplication of the conquest of the world of color, which has occurred in the last fifty years, by the greater conquest of the world of scientific medicine! A brilliant beginning has been made in this campaign by the preparation of excellent substitutes for cocaine, less toxic than cocaine itself—by the elaboration of salvarsan, by the isolation in our own country, and the artificial production, of adrenalin, a vital regulating principle produced by an organ, the suprarenal capsule, in our bodies. The isolation and exhaustive study by Kendall of the active principle of the thyroid gland, which no doubt will be followed by its artificial preparation, is a second brilliant instance of American success in this great field! When we consider the countless number of animal preparations—gland extracts, serums, and antitoxins—the pure active principles of which are all we really want, but which are injected into us or fed to us, with an extraordinary amount of unnecessary and often harmful animal matter, we can realize what a boon to humanity this line of effort really means. Let me emphasize again, it is chiefly a matter of wise and foresighted legislation to make our independence and possibly our leadership in this great field possible—we have proved that we have the scientific ability—it is a question only of putting this work on the basis of an established industry!"

* * *

"Now, thoughtful men in our society, looking ahead, see that this great uplift in our scientific life is facing dangers which, unless they are met frankly and effectively, will bring on a period of depression which will be a grave menace to all the varied fundamental interests in the life of the nation that depend on chemistry.

"The first and greatest of these menacing developments has its root in the recent unprecedented demand of our industries on our schools for research men. From university after university, from college after college, the combined lure of great research opportunities and of much larger financial returns has taken from our academic life far too many of our most promising young men, the very men on whom the country has been depending for the filling of our great university chairs as the older men now holding them gradually will age and retire. Unless prompt measures are taken we shall witness in a few years such a dearth of first-class tried material for professorships that second-rate men will be placed where the national welfare needs the best we have, and third and fourth-rate men will be occupying positions in which we should have young men of the highest promise in the period in which they are reaching full maturity. Indeed, it is greatly to be feared that even now we are witnessing gradual lowering of standards. It would be futile to appeal to our industries not to call the men they need, although in the not distant future they will suffer most severely from the situation which is developing, if the present tendencies remain unchecked. The only possible source of relief lies, I believe, with the presidents and trustees of our great universities and to these the second main plea of this privileged discussion is addressed. These authorities should recognize the fact that their institutions have now entered a period of severe competition between the industries and academic life for chemists of the highest type and greatest promise. They have already learned the only method of meeting this kind of competition successfully, for they have faced the same problem in two other professions, medicine and law. In the face of the tremendous financial attractions of the practice of either of these professions our most progressive universities have simply put their law and their medical faculties on a higher, more nearly professional scale of endownment of professorships than obtains for other faculties. They must, it seems to me, take the same measures with their chemistry staffs; it is primarily a question whether they can be awakened to that need now or whether they will let the country suffer from their lack of foresight and let us learn from the most efficient of our teachers, bitter experience. Wise provision now would not only safeguard our present standing in a critical period of our history, but in this time when the importance of chemistry has been brought home to our young men as never before, the new attitude, properly announced, would attract a larger proportion of the men of brains, talent and ambition, who enter professional life but tend to study law or medicine as holding out much greater opportunities for satisfying their ambitions.

"Adequate compensation is important for a research man—and to his type in university and college I must restrict my remarks—it is important both from the point of view of his self-respect and also especially for the sake of comparative freedom from worry concerning a fair provision for his family. But inadequate compensation is not the only danger seriously threatening the outlook for chemistry in our universities. Let us remember that healthy progress in our science is dependent primarily on university men pursuing great lines of original investigation. It is true that we have now well-endowed national institutions of research, such as the Rockefeller Institute and the Carnegie Institution, but universities cannot afford to surrender to these the main burden of insuring progress in the theory of our science, because these are not teaching institutions. To take from our universities the choicest of our research men would deprive our young men of that inspiration and fertilization of their minds in the period of their greatest acceptiveness, which early intimate association with great investigators alone can give. To my mind it is clear that if universities would fulfill their highest mission they must remain the seats of the best type of research."

* * *

"I have dwelt on the details of this great problem which is confronting our society, because I would protect the outlook for the growth and success of theoretical chemistry in our country by every means in my power. We have a splendid record; we are easily leaders in the domain of knowledge based on the exact determinations of atomic weights—a knowledge which leads among other results to habits of more exact, more critical methods in all fields of our science. Arrhenius told us that America is leading in the difficult work of the rigorous examination of the theory of ionization and of establishing it on a finished basis. The development in the field of free energy relations is more intensely cultivated here, I imagine, than in any other country. In the application of modern theories of atomic structure and of the electron theory of valence to all branches of chemistry, especially also to organic chemistry, we are, I believe, easily in the front. Our very youth, as a people, has preserved to us in science as in national sentiment, that whole-hearted enthusiasm for ideals, which in world politics has made us the most altrustic nation on the face of the earth and which in science finds its expression in the pursuit of knowledge for the sake of the pure truth alone, a pursuit characteristic of the best research in our universities and colleges!

"And so let me conclude my remarks on the outlook for chemistry in America by emphasizing that we have a goodly heritage of success both in our great industries and in our great universities, which will form the safe basis of a brilliant future, if we will but approach the problems of the moment and of the immediate future in characteristically American fashion with a spirit wisely combining altruistic principles with practical, worldly common sense. This means the "square deal" in industrial life for the product of the brains of the research chemist, combined with wise laws to insure to capital a fair and tolerably safe return for investment in chemical industries, needed to make our country chemically independent. And it means too the placing of chemistry in our universities on a plane with the other great professions, law and medicine, in order to hold in this great science, so important for the welfare of the nation, the needed numbers of men of brilliant minds and energetic ambitions—combined with the devotion on their part to the search for the truth, to the establishment of the great laws of our science, for the sake of that truth, that science alone."

"Everyman's Chemistry."

THE CHEMIST'S POINT OF VIEW AND HIS PRESENT WORK,

By Ellwood Hendrick.

Harper & Brothers, 1917. Pp. 374. Price, $2.00.

There are scores and scores of "popular chemistries" in various languages, in which the emphasis rests sometimes upon the noun and sometimes upon the adjective.

It is not often that the well-equipped scientist possesses the happy gift of visualizing fact and theory from the standpoint of the man in the street. The ability is possessed by the French more generally than by other nations. It is difficult for Frenchmen, even when dealing with exceptionally abstruse matters, to be otherwise than clear and interesting. Liebig, among German chemists, possessed the faculty in a high degree, and it was one secret of his marvelous influence upon the development of his science. Geoffrey Martin, in Great Britain, has done excellent work in popularizing chemistry. Many Americans are indebted to the works of Youmans half a century ago, or the more recent volumes of Sadtler, and especially of the late Robert Kennedy Duncan, for inspiring guidance into the mysteries of chemical science.

In the present book we encounter practically a novelty in chemical literature. It is not only replete with fact, well arranged and lucidly presented, above all accurately stated, and has sufficient theory outlined in an easily understandable manner; but the element of human interest is constantly in the foreground and the book bubbles over with humor.

There is scarcely a page which does not evoke a smile upon the face of the reader, whether he be a Ph.D. of many years standing or a novice gleaning his first ideas of what chemistry means. Quaint allusions, novel descriptions, vivid similes, dramatic comparisons, all combine to render the work as fascinating as a romance, while impressing its contents firmly upon the memory.

A striking head for a chapter is "The Redheaded Halogens." It is quite understandable from the remark "We are wont to attribute to men and women having auburn hair a certain quickness in response to a stimulus."

Imagination and memory both are aided by such epigrams as: "Fluorine is the young devil, iodine is the old man with a past"; "Tin is one of the very trickiest of metals"; "$CaCl_2$ is one of those chemicals that is still looking for a job"; "Atoms are given to polygamy and polygandry as matters of entire propriety, and if it were not for the fact that we cannot imagine atoms as having sex, the way they shift about in their matings would scandalize any community"; "The benzol ring is as whimsical as an Irish lass"; "The isonitriles smell to high heaven"; "The (adjective deleted by publisher) stuff known as cocoa powder is the pulp of the cocoa beans with nearly all the oil pressed out"; "You can't pick mercury up, and that is a good way to prove that it is a liquid"; "When you come right down to it, some metals are no better than nitrogen in the way of being plain-spoken and easily understood"; "Iron is not found in the pure state because in time the oxygen will get it—whether it watches out or not."

With all this whimsicality and colloquial familiarity the book is well-balanced, carefully arranged and eminently adapted to meet the needs of a multitude of busy people, desirous of gaining an intelligent acquaintance with the mass of chemical phenomena in the midst of which our life is passed. The number of these increases rapidly as the world realizes to an increasing extent how largely the titanic conflict, now raging, is a war of chemists.

Mr. Hendrick terms his book a ramble through "that branch of philosophy and poetry which has to do with the Ways of Stuff," and it is a correct characterization. He has succeeded admirably in producing a scientific manual which is brimful of human interest.

The work is without illustrations. It is a question, in these days, whether the full value of a popular treatise on chemistry is secured without an ample appeal to the eye. T. H. N.

A French Society of Chemical Industry.

The British Society of Chemical Industry has become a powerful agency for the development of technical chemistry in the British Empire, and even throughout the world. It has strong sections in this country as well as in the British colonies. The organization has worked harmoniously, side by side with "The Chemical Society" of London, devoted more exclusively to the interests of pure chemistry, and the oldest of our chemical societies.

France has had for many years a society similar in aims to the last mentioned, "Société chimique de France," (formerly the "Société chimique de Paris"), which has been of the greatest value in furthering the interests of the science in the French Republic.

Recently, French technical chemists felt that the time was ripe for organizing a separate body devoted to applied chemistry, more especially in connection with the strenuous efforts now made to render their country entirely independent of German sources of chemicals. They have accordingly established the "Société de Chimie Industrielle," with headquarters at Paris, 49 rue des Mathurins. The president is M. Paul Kestner and the secretary M. René Engel. It is interesting to note in the case of the above, as well as of several other officers of the society, the presence of Alsatian names. Beginning with Adolph Wurtz, Alsace has contributed for the past half century an exceptionally large number of gifted chemists to France.

The secretary of the new society, M. Engel, was a member of the French Scientific Mission to the United States. A number of leading American chemists, after conference with him, have felt that it would be most opportune to organize an American section of the French society, and that in this way we might do much to strengthen the efforts of French colleagues at a moment when support, moral and financial, would be of the greatest assistance.

Over thirty chemists form the nucleus of the new American section and their number is steadily increasing. The Organization Committee has headquarters at the Chemists' Club, 50 E. 41st St., New York City, and furnishes full information to all inquirers.

There is no doubt but that a strong section will be formed, and it will do much to establish closer ties between the chemists of the two republics. The happiest results have followed the existence in this country of sections of the corresponding British society.

Government Aid to Chemical Research.

There is a strong feeling in this country that much might be done to further the rapid growth and expansion of the artificial color industry by highly organized research on the part of governmental agencies. To some extent this feeling has been reflected in the legislation of the past two years, in which provision has been made, on a somewhat modest basis it is true, for investigations in this field by the Bureau of Chemistry in the Department of Agricultural.

In this connection it is interesting to note the attitude toward the question taken by the British "Commitee for Scientific and Industrial Research," organized by the Privy Council.

Much of the activity of the committee has been directed to stimulating cooperative research in various industrial branches. This has not been easy, for the traditions of British industrial development are firmly based upon pronounced individualism.

In the committee's report for the fiscal year 1916-1917 the position of the leading chemical industries is submitted to a careful analysis, and the following conclusions are drawn:

"We have remarked that those industries which call for the most complex organization, and are most in need of scientific guidance, if they are to meet modern conditions sucessfully, are, for the most part, those in which the smallest progress has been made towards research on a cooperative basis. We refer to that large group of what may be called the chemical industries. At the one end of this group we find a growing movement towards financial combination—e. g., among the highly developed heavy chemical and allied industries. Financial combines or fusions of scientific industries on the scale we are witnessing will certainly render cooperation for research alone less attractive, if not unnecessary. At the other end of the scale are industries, like those of pottery and glass, which have been driven by adversity to seek the aid of science, and have only been able to meet the cost by operating together. Between the two extremes is a large number of industries, some of them wealthy, which appear to be uncertain in which direction to move, and would probably prefer to move in neither.

"The German chemical industry, with its powerful firms engaged in handling the primary raw materials through all their intermediate stages up to the manifold but closely related final products—explosives, dyes, essences, drugs, antiseptics—would not be suited for cooperative research, though it may be prepared to go far in the direction of financial fusion—a mere continuation of the previous line of development. If, as in this country, conditions are in many respects specially favorable to cooperation in the conduct of research, the State is, we think, justified in encouraging development along these lines by means of monetary and other assistance."

The ideas formulated by the committee are especially applicable to this country. Even more than in Great Britain, we need the powerful assistance which can be given our coal-tar chemical industry by a highly perfected scheme of research involving the close cooperation of the different units concerned as well as of governmental agencies. Time is an all-important factor. The industry must be rounded out as rapidly as possible while the exceptional opportunity is afforded of freedom from competition.

It is hardly correct to state that the German chemical industry, and more particularly the German color industry, is not suited for cooperative research. Undoubtedly much has resulted from the well organized research laboratories of the few big companies. The general progress has, however, resulted from the effective cooperation of the expert staffs in the chemical laboratories of the universities and schools of technology—all highly subsidized by government appropriations. These have served as clearing houses, so to say, of the results of individual inititative. They have focussed scientific and technical attention upon the great possibilities attendant upon newly developed classes of reactions. They have supplied a vast mass of closely related scientific fact and theory absolutely essential for swift progress along economic lines.

In a very real sense there has been close and effective cooperation between the scientific agencies of the different German States and the various factors of the coal-tar chemical industry. The relations of the latter to means of military power have intensified the connection.

The same may be said for conditions existing in Switzerland, where the situation of the color industry is relatively so strong.

One feature of cooperation, formulated by the British Committee, is eminently practical, and could well be imitated by any similar organization in this country when dealing with industries which have failed to appreciate the importance of chemical control and assistance.

The Committe is prepared to attach a young research worker to the works laboratory of an industrial plant for an agreed length of time, divided into three periods. During the first period the Committee would pay the salary of the worker, during the second the Committee would pay half, and during the third the firm would pay the whole.

Full details of this scheme remain to be elaborated. It would appear, however, to be a very practical method of demonstrating to the management of a plant the financial value of expert chemical assistance.

During the past year the British Committee has expended $70,000 and has rendered aid to forty-four different industrial researches.

Toluene from Illuminating Gas.

The question of removing benzene and toluene from the illuminating gas of our cities, for the purpose of isolating therefrom the toluene and placing this at the service of the munition makers, is now being pushed actively.

The War Department claims that it will need at least 300,000,000 pounds of toluene annually to provide the proper amount of high explosives for an army of 1,000,000 men.

The present annual output of toluene from by-product coke oven plants is about 80,000,000 pounds. If all available toluene from American gas works were recovered, the amount would not exceed 150,000,000 pounds. This means that under the most favorable conditions, we cannot secure from the distillation of American coal, as now carried on, more than 230,000,000 pounds of toluene. This is materially below the needs of our own army, not to mention the requirements of the allies.

In order to meet the demands of the War Department, the matter is under active discussion by the gas companies of New York. There seems to be a willing readiness to install the requisite recovery plants. A chief difficulty encountered is the necessity of changing the existing candle-power standard. It is proposed to substitute in its place the present British thermal unit.

The Public Service Commission has started a series of hearings on this subject. In all probability consumers of gas will soon be obliged to content themselves with a product of less luminous power, but nearly equal heating power. In view of the widespread use of incandescent mantles, and of gas for purely heating purposes, this may not be such a serious deprivation.

The American Supply of Coal Tar Grudes in the Future.

There is a steady increase in the number of by-product coke ovens in this country which shows that American metallurgical interests are firmly convinced that the wasteful bee-hive type must disappear at an early date. The amount of coke produced in retort ovens in 1914 was 32.5 per cent of the total quantity. In 1915 it was 33.8 per cent, in 1916, 34.9 per cent. During 1917 it is estimated at 40 per cent.

This means that under normal conditions the American output of coal-tar crudes will be far in excess of any domestic industrial demands. .

In 1914 some 12 by-product coke plants were equipped to recover light oil or crude benzol. The total annual output was less than 7,500,000 gallons. To-day all of the 52 by-product coke plants in the United States, with one exception, are provided with benzol scrubbers. The output of light oil is now about 60,000,000 gals. This yields nearly 10,000,000 gals. of refined toluene.

At present all of this toluene is required for the manufacture of trinitrotoluene, for use as an explosive, and much of the benzene is transformed into picric acid.

When the war demand for these hydrocarbons ceases, the question arises as to the profitable use for the great output. The coal-tar chemical industry of our country is steadily expanding, but for some years it cannot consume in the manufacture of synthetic colors, medicinals and allied compounds, more than about one-tenth of the light oil now available.

The logical result will be to use the large available excess as motor fuel. Benzene alone, or preferably when it contains 10 per cent of toluene to lower its freezing point, is an ideal fuel for motor engines, equal if not superior to gasoline. Benzol recovery plants can be operated with a fair margin of profit on gasoline prices, and the reaction of this additional source of motor fuel on the steady tendency upward of gasoline rates will be generally welcomed.

Of other by-products of the coke ovens, obtained from the tar recovered, there would seem to be no question that all of the phenol recovered can be profitably used, and that there will be an ample market for the creosote oil. But a relatively small quantity of the cresols present in tar oils need to be separated and refined for the needs of color manufacturers.

It is quite a problem how to utilize completely the available naphthalene, which constitutes about 8 per cent of coal-tar, and can readily be isolated from the carbolic and heavy oils. The actual amount needed by color works is considerable, but represents only a fraction of what is available. Prior to the war most of our refined napthalene, for use against moths, was imported. There is now sufficient protection on the article, so that current needs will be covered by the domestic production. These total needs are, however, far from equaling the large quantity available, if there is commercially an inducement to refine it. It is to be hoped that our coal-tar chemists will gradually work out new opportunities for the economic utilization of this abundant hydrocarbon.

Anthracene is present in much less amount and constitutes not over 0.3 per cent of coal-tar. This quantity will, however, amply suffice for the manufacture of all the alizarin, and the various anthracene colors which the American consumption requires and have a large surplus.

There is much to indicate that the activity of chemical research along tinctorial lines will find its best results among anthracene derivatives. Categories of new dyes, allied closely or remotely to the algol, indanthrene and similar colors, may be evolved, which will call for increasingly large amounts of anthracene.

In regard to the coal-tar crudes, called for in relatively small amounts, such as xylene, phenanthrene and carbazole, the supply will be far in excess of any prospective demand, and but a small proportion will need to be isolated and refined. There is little or no attempt made thus far by our American color makers to utilize phenanthrene or carbazole, but at an early state they may be called into requisition. Xylene is now used to some extent and will be used more freely. There will remain, however, a large surplus which can probably be used to a greater or less degree as a motor fuel in connection with benzene.

The chief problem to be solved will apparently be that of the complete and profitable utilization of available naphthalene.

Apart from the use of the coal-tar crudes, there is, also, a certain problem to be worked out in connection with the vast amounts of residual pitch remaining from the distillation of coal-tar. In Europe his has been solved by the extensive manufacture of briquettes from coal waste, using pitch as a binder. There is no reason why this manufacture in the United States should not expand far beyond its present limits.

Wages in the German Chemical Industry.

There has been a steady increase in the rate of wages paid to operatives in all branches of industry in Germany during the war, just as has been the case in other belligerent lands. The average increase, during the first two years of the war, was for males 46 per cent and for females 54 per cent. Strange to say the increase has not been so marked in the chemical industries as in case of machinery, metallurgy and especially electrical branches. The average daily wage of men in the chemical industry rose from 5.14 marks ($1.25) in March, 1914, to 6.90 marks ($1.64) in September, 1916, an increase of 34 per cent. For women the increase was from 2.36 marks ($0.45) to 3.55 marks (($0.71), or 50 per cent. Men engaged in electrical works had an average increase of 65 per cent.

The rise in wages is, however, very far from keeping even step with the increased value of food which costs double the prices of 1914.

COAL-TAR INTERMEDIATES

The Inspection and Testing of Trinitro-Toluene.*

By K. K. Stevens

Trinitro-toluene, although long known to chemists, is comparatively new in the field as a military explosive, and for brevity is designated by various trade names, such as "Trotyl," "Tritol," "Trinol," "Tolite," "Trilit," and commonly known as TNT.

Picric acid or trinitro-phenol was, and is still, used to a large extent as the principal explosive of this class, under the names of "Lyddite" and "Shimose." Picric acid and TNT belong to the "brisant" or shattering class, and are used largely in the manufacture of shells, torpedoes, mines, and, either alone or as components, in detonators or "exploders." The chief disadvantage in the use of picric acid is its tendency to form very sensitive picrates with the metals of shells, etc., and necessitates strict specifications for these materials.

TNT has several advantages over picric acid, viz.:

(1) Inertness towards heavy metals, in direct contrast to the picric acid, although caustic potash or soda form compounds with TNT which will cause it to explode at even 160° C.

(2) Lower fusion temperature, which allows pouring to be done at 81° C. or lower, while picric acid requires a temperature of 115° to 120° C.

(3) Stability in storage; it can be stored indefinitely without change in composition.

(4) Insensitiveness to shock of impact or firing, so that it can be safely handled and transported. A rifle bullet fired through a case of TNT has no ex-

---

*From the Journal of Industrial and Engineering Chemistry, August, 1917.

plosive effect, and covering with either sand or water has no effect on shattering force.

The velocity of detonation is less than picric acid, 7,100 meters per second against 7,600.

The expansive force test shown in the "Trausel lead block" method gives for TNT 218 cc. against 228 for picric acid. These figures may vary with different grades of material and are merely cited for comparison.

The lower expansive or shattering force is in some instances advantageous; for example, a shell blown into very small pieces will not have the disastrous effect produced if the fragments are larger.

Used in detonators, TNT replaces the more expensive mercury fulminate; e. g., in a No. 7 cap, containing 1.5 g. of fulminate, 0.7 g. of TNT will replace 0.5 g. of fulminate.

TNT is also used as a component of many explosive mixtures, having greater effect if combined with compounds like chlorates and nitrates These furnish oxygen for the complete combustion of the TNT, which is decidedly lacking in oxygen, and when exploded alone gives a dense black smoke.

Inspection.

TNT is on the market in two grades, primarily, crude and refined. The crude has not been recrystallized from solvents, while the refined has. Of these two grades, there may be several other grades based on the melting point (M. P.) or usually the solidification point (S. P.).

The crude TNT is the more common in the U. S., and when purchased by foreign governments is shipped crude and either refined or blended with other substances. The greater bulk of TNT made, up to very recently, has been shipped crude, probably only three plants in the U. S. manufacturing the refined grade in any quantity. In the different plants the product is obtained in lots of approximately 2,200 lbs. each, called "runs."

The specifications usually call for containers, such as cases or kegs, which hold from 60 to 100 lbs., are lined with oiled paper, and numbered as to shipment, "run" and case. The inspector may be expected to check the weights, and take samples for analysis.

Sampling.

Samples should represent amounts of 4,000 lbs., and for convenience a composite sample from two runs is often taken. The cases are selected, opened, the samples taken from different parts of the case, mixed, and three 1-lb. bottles filled: one each for buyer, seller, and referee, the latter's bottle being sealed by the buyer's inspector.

Testing.

COLOR should be light yellow for crude, cream for refined.

Comment—The color changes rapidly when exposed to strong light, sunlight changing it from yellow to orange in 15 to 20 minuts, although usually the deeper shades of yellow are not an indication of impurity. The brownish grades should be inspected, though not necessarily condemned in the crude grade without confirmatory tests.

In the refined grade the color may vary with the solvent used in recrystallizing, but should usually be of a light cream, melting to a clear light brown, not darkening appreciably at 100° C. for 2 hours.

FINENESS—For crude, 90 per cent shall pass through a 10-mesh sieve. For refined, 99 per cent shall pass through a 12-mesh sieve. For exploders, all shall pass through a 30-mesh sieve.

Comment—The crude may contain frequently 7 to 8 per cent of lumps larger than specified, but usually is O. K., always being sieved before packing, and the lumps forming on the sides of the crystallizing tub have been allowed, intentionally or accidentally, to get into the sieved product.

MOISTURE shall not be more than 0.10 per cent for crude or refined (some specifications allow 0.15 per cent) and shall be determined by drying 2 g. over sulfuric acid for 24 hours.

Comment—The method is efficient and will remove as much as 30 per cent of moisture in the time specified.

ACIDITY—There must be no acidity. This determination is made by shaking 10 g., melted, with 100 cc. boiling distilled water, allowing to cool, pouring off the water extract into a flask, and reserving. The operation is repeated with 50 cc. water, adding the second extract to the first. The combined extraction is titrated with N/12 caustic alkali, using phenolphthalein as indicator.

Other specifications, less definite, are as follows: Shake 5 g. with 100 cc. of distilled water in a 100 cc. graduated cylinder one minute, add blue litmus paper and let stand 30 minutes, with occasional shaking. The paper must not show any acid reaction at the end of this time.

One specification allows 0.03 per cent acid calculated as sulfuric.

Comment—The method of the first specification seems better, although any sodium bicarbonate washing (not used at present) will give acid reaction at this point, whereas methyl orange will indicate only the mineral acids. The litmus paper shows acidity with phenolic compounds as well as acids, but if the determination is carried out as specified, there will be no color to the litmus paper, i having been completely bleached, and any acid reaction is more or less doubtful. The method may be modified as follows: Shake 5 g. with 400 cc. distilled water 1 minute, *filter*, let stand 5 minutes and add the litmus paper. Any acid reaction will be detected in 2 minutes. The litmus might be used instead of titrating in the first method.

INSOLUBLE MATTER must not exceed 0.15 per cent, as determined by boiling 10 g. with 150 cc. of 95 per cent alcohol, collecting on weighed

Gooch crucible, washing with not more than 150 cc. of 95 per cent alcohol, drying at 95° C. 1 hour and weighing.

Some specifications call for benzene as the solvent and allow 0.1 per cent for refined, 0.15 per cent for medium, and 0.2 per cent for crude.

Comment—The method is efficient.

Turbidity in the wash water is one cause for high insoluble matter, and another is allowing the TNT to stand too long in the lead-lined wash tanks, the acid attacking the lead and forming lead salts.

ASH IN CRUDE TNT must not exceed 0.10 per cent, determined by lighting 1 g. in a platinum crucible, allowing to burn slowly and igniting completely, precaution being taken to prevent loss of ash.

Comment—The sample should be heated, ignited directly with the flame and allowed to burn without first melting. If melted and then heated further the sudden combustion will expel it from the crucible.

The size of the sample should be about 2g., taking into consideration the low percentage of ash present.

The residue, called "insoluble matter," might be conveniently used for the ash determination.

Some specifications call for sulfated ash, probably to avoid loss of potassium or sodium salts during ignition.

ASH IN REFINED TNT for exploders must be less than 0.05 per cent.

NITROGEN—Crude TNT must not contain less than 18.00 per cent of nitrogen determined by the Dumas combustion method.

Refined TNT must not contain less than 18.2 per cent. of nitrogen determined by the Dumas combustion method.

Comment—The Dumas method, standard for nitrogen, requires little comment, results being very satisfactory, although it is necessary to make determinations on a substance of standard nitrogen content.

The method requires from 1½ to 2 hours, and unless the chemist possesses several furnaces, not very many determinations can be made daily.

For the nitrogen determination of many organic compounds, the Gunning-Arnold method or a modification of it has been used. The only modifications reported to be satisfactory for trinitro-toluene, or other nitro compounds, are the zinc-dust reduction by W. C. Cope, U. S. Bureau of Mines, and the use of nitron as a reagent, by W. C. Cope and J. Barub, *J. Am. Chem. Soc.*, 39 (1914), 504-14.

The nitrogen determination is important, although if the melting point or solidification point is up to specifications, the nitrogen is seldom below.

In many instances it as a common practice to average several samples for the determination of nitrogen.

DIPHENYLAMINE TEST—Crude TNT shall contain no products which will give the nitric acid reaction with the sulfuric solution of diphenylamine. The determination is made by shaking with 50 cc. distilled water in a graduated glass-stoppered cylinder, letting stand for 15 minutes, filtering and testing a few drops of the filtrate by addition to a diphenylamine solution. No nitric acid reaction should be obtained.

Comment—The blue color, characteristic of this reaction, is readily recognized and the test is extremely delicate.

Care must be taken that vessels are free from traces of nitric acid or nitrates.

Since other oxidizing agents, such as chlorine, chlorates, bromates, etc., will respond to this test, it is of more value, as a negative test, and fairly positive because the oxidizing agents mentioned are not likely to be found in trinitro-toluene. A pale blue color is not confirmative; and color should be deep blue.

Melting Point.

THE MELTING POINT of crude TNT must be 75.5° C. or higher.

Note—This is the mean, some specifications call for a melting point of 74.5° C., others 76.5° C.

Medium TNT must have a melting point of 79.5° to 81.5° C.

Refined TNT for exploders must melt from 80° to 81.5° C.

Comment—Methods for obtaining melting points are not usually given in the specifications, but it is absolutely necessary that a definite procedure and definite apparatus be agreed upon. The following points should be taken into consideration: calibration and stem correction of thermometers, size of tubes, amount of substance taken, degrees of melting at which reading is to be taken, rate of melting and vessel or liquid to be used as bath.

The following is given by H. B. P. Humphries, Engineer:

APPARATUS AND METHOD—A beaker of 1,500 cc. capacity should be filled ¾ full with distilled water, heated by an adjustable Bunsen, arranged with a mechanical stirrer, with the center of the blade level with the thermometer bulb, clearing it by ½ in. The thermometer should be graduated in tenths of a degree, and lowered so that the bulb is 1-3 the height of the beaker from the bottom and 1 inch from the side.

Tubes should be made from thin-walled 6 in. x ½ in. test tubes drawn out into 1-16 in. internal diameter, cut into 3 in. lengths, and sealed at one end.

Set the stirrer going and heat until the temperature is about 15° C. below the melting point. Meanwhile introduce a ¼ to ⅜ in. column of the powdered sample (previously dried at a suitable temperature) into a tube and tap and tamp down gently. Attach the tube to the thermometer by a rubber ring so that the center of the column of material is level with the center of the thermometer bulb, and replace the thermometer as before. Reduce the heat so that the temperature rises 1° in 2 or 3 minutes. The slower rate should be adopted if several determinations are made at the same time.

Readings—Note the temperature when:

(*a*) The first globule of melted material is observed;

(*b*) The material is half molten and half unmelted;

(*c*) The melting is complete and a clear liquid occupies the tube.

Record these readings and call (*b*) the uncorrected melting point.

CORRECTED M. P.—Correct the readings for

(*Concluded on page 64*)

ARTIFICIAL COLORS

Artificial Colors Used in the United States

By H. Walford Martin

When the so-called "Dyestuff Census," or list of the "Artificial Colors used in the United States," was prepared by the Bureau of Foreign and Domestic Commerce in 1916, it was desired to supplement the statistical matter collected on our imports for the fiscal year 1913-14, by summaries classing the data under the more specific heads of color, methods of application, etc. The urgent demand for a speedy appearance of the "Census" rendered this impossible. No classification was attempted beyond the fundamental division into groups based on chemical nature, as employed in the standard "Farbstofftabellen" of G. Schultz, in general use among tinctorial chemists.

In the September issue of the "Journal of the Society of Dyers and Colourists" Mr. H. Walford Martin publishes the results of a careful grouping of the data furnished by the "Census," regarded from the standpoint of the dyer.

These groupings are of great value and throw a most interesting light on the relative importance of different dyes and different classes of dyes, in the American consumption of synthetic colors.

On the basis of color, the dyes imported in 1913-14 may be grouped as follows:

	Per cent.
Black	36
Blue	32
Red	9.3
Yellow	7.5
Brown	4.
Orange	2.5
Green	2.5
Violet	2.2

On the basis of method of application the percentages are as follows:

	Per cent.
Direct Cotton	21.6
Indigo	21.3
Sulfur	16.8
Acid	15.8
Mordant	11.0
Basic	6.0
Vat	4.0
Lake	3.3

These figures explain easily why the efforts of the young dyestuff industry were so largely directed in 1915 to securing, first of all, an ample output of blacks, and were then gradually led to the blues.

T. H. N.

THE UNITED STATES AS A DYESTUFF MARKET.

Until the publication of the U. S. Dyestuff Census there was no authoritative record of the dyestuffs which have commercial importance or of the extent to which they are used. As a consequence the text books contain elaborate descriptions of dyestuffs brought out with great expectations which never materialized, while colors which command extensive sales are passed over in a few sentences or are not mentioned at all. The field is, however, so extensive and so intricate that many of the figures are incomplete and misleading. Nevertheless the outstanding features of the situation can be presented with substantial accuracy even though approximately 200,000 lbs., say 1%, of the total importations, have not been identified by the writer, and in other cases importations have not been correctly identified.

In the lists which follow the first figure is the number assigned to the dyestuff in Schultz's 1914 "Tables," the second figure represents the importation in pounds for the year ending June, 1914. The firm name has been attached where it appears that the figures substantially represent the importations of one factory. Where the products of many factories have been imported, the attempt has been made in numerous cases to use the designation of the firm with the largest share in the business. The classifications are of course arbitrary and overlap each other.

(1) Alizarine Colors, Etc.

This includes the chrome-topped colors, the acid Alizarine colors, of which certain are used as ordinary acid colors, the fast one-dip colors, not generally used as acid colors.

In *Red* the most important group is Alizarine with importations of 359,043 lbs., followed by 59,875 lbs. of one-dip reds, 24,139 lbs. of chrome-topped reds and 10,917 lbs. of acid Alizarine Red. The most important colors are:

778	Alizarine paste	302,836
780	Alizarine Red W pdr	53,154
202	Palatine Chrome Red B (B)	7,374
29	Eriochrome Red B, AW, (G)	5,491
182	Brilliant Sulphon Red B, 5B.	
	Fast Sulphon Violet 4R (S)	4,871
400	Acid Anthracene Red 38	14,120
	Milling Red 6BA, GA, (Ber)	4,540
	Alizarine Rubinol R, 5G (By)	10,917

In *Orange* the chrome topped group leads with importations of 40,159 lbs. followed by 14,739 lbs. of Alizarine Orange and 11,977 lbs. of one-dip orange. The most important colors are:

		Pounds
779	Alizarine Orange paste and pdr	14,739
58	Mordant Yellow 3R	37,544
250	Milling Orange	10,427

In *Yellow* the most important group is the chrome-topped, with importations of 423,466 lbs., followed by 18,290 lbs. of one-dip yellow and only 5,884 lbs. of Alizarine Yellow. The most important colors are:

		Pounds
773	Anthracene Yellow	5,046
294	Fast Mordant Yellow G	3,678
102	Diamond Flavine G (By)	23,089
96	Chrome Fast Yellow	15,165
177	Mordant Yellow	85,003
“	Alizarine Yellow O (M)	59,000
“	Salicine Yellows (K)	23,068
“	Anthracene Yellows (C)	16,050
48	Alizarine Yellow 2G paste and pdr	152,884
	Sulphon Yellows (By)	7,698
	Milling Yellow O	10,592

In *Green* the Alizarine Cyanine Green group leads with importations or 135,513 lbs., followed by 65,335 lbs. of chrome-topped green, 32,184 lbs. of Alizarine Green and 8,626 lbs. of one-dip green. The most important colors are:

		Pounds
805	Alizarine Green S (M)	15,885
808	Alizarine Green S paste (B)	11,096
601	Coeruleine paste and pdr. (B)	3,404
865	Alizarine Green CG Ex. etc. (By)	124,095
863	Anthraquinone Blue Green BXO (B)	6,552
276	Palatine Chrome Green G (B)	19,665
“	Diamond Greens (By)	8,622
	Chrome Fast Greens (I)	12,943
	Eriochrome Greens (G)	7,220
91	Anthracyl Chrome Green D (D)	4,596
	Salicine Dark Green CS (K)	5,458

In *Blue* the Alizarine Blue group leads with importations of 682,697 lbs., followed by 347,465 lbs. of the Sulphoncyanine group, 276,679 lbs. of the chrome-topped blues and 134,444 lbs. of the Alizarine Saphirol group. The most important colors are:

		Pounds
803	Alizarine Blue WX paste	16,575
804	Alizarine Blue SB (M)	12,400
	Alizarine Blues, various	302,319
	(Alizarine Cyanides etc.)	
	Alizarine Pure Blue DPH (M)	31,000
789	Anthracene Blues WR, W3R, (B)	107,778
800	Anthracene Blues WB, WG, (B)	54,712
801	Anthracene Blues SWGG, WN, (B)	22,444
	also includes SWR, SWG, of 789, 90	
	Anthracene Dark Blue W (B)	4,198
	Alizarine Dark Blue S, DR (M)	6,300
667	Brilliant Alizarine Blues, etc	19,060
599	Galleine pdr	15,404
626	Gallocyanine	78,253
163	Chrome Blue	Cp. Acid Color List
163	Chrome Blue	Cp. Acid Color List
	Probably 100,000 lbs. Carmoisines are used chrome-topped.	
	Palatine Chrome Blue 2B WBB (B)	42,244
	Acid Chrome Blue 3G 2R 5R (By)	25,633
	Anthracyl Chrome Blue 2B D (D)	24,979
	Chrome Fast Blue 4B (Ber)	23,585
	Omega Chrome Cyanine R (S)	21,001
	Fast Mordant Blues B R (M)	17,000
	Salicine Blue B (K)	16,224
	Metachrome Blue B, G (Ber)	14,301
	Chrome Fast Cyanine G (I)	9,511
	Anthracene Chrome Blues (C)	5,027
	Anthracene Acid Blues (C)	4,968
51	Eriochrome Azurol B (G)	21,070
552	Chromal Blue G conc. GC (G)	1,235
257	Sulphoncyanine	159,024
	Indocyanines (Ber)	70,495
	Wool Fast Blue BL GL	28,865
188	Sulphon Acid Blue R	45,038
189	Sulphon Acid Blue B	35,112
858	Alizarine Blue SAP SAE etc	79,679
855	Alizarine Sky Blue B pdr. (By)	19,471
851	Alizarine Direct Blue EB ESB ESR (M)	10,201
859	Cyananthrol R (B)	18,792
	Alizarine Uranol 2B R, (By)	4,947
856	Alizarine Astrol S (By)	
852	Alizarine Irisol R (By)	

Obviously misled by the names Alizarine Blues AS & JR, these two dyestuffs are included in "Alizarine Blues various" given above.

In *Violet* the importations are insignificant, viz., 8,457 lbs. of various Gallocyanine products for calico printing, 6,881 lbs. of various chrome-topped violets and 1,202 lbs. of Anthraquinone Violet (No. 853).

In *Brown* the chrome-topped group leads with importations of 207,385 lbs., followed by 123,861 lbs. of Alizarine Brown. The most important colors are:

		Pounds
782	Alizarine Brown paste and pdr	115,586
89	Metachrome Browns B BL BRL (Ber)	58,344
88	Acid Anthracene Browns (By)	33,053
154	Palatine Chrome Browns (B)	18,264
	Chrome Fast Browns (I)	12,204
	Oxychrome Browns (GrE)	10,490
	Anthracene Chromate Browns (C)	9,548

In *Black* the chrome-topped group leads with importations of 1,617,432 lbs., followed by 749,636 lbs. of Alizarine Black, 171,795 lbs. of the Sulphoncyanine group and 7,554 lbs. of Acid Alizarine Gray. The most important colors are:

		Pounds
774	Alizarine Black S SR WR (B)	136,461
806	Alizarine Blacks (M)	229,500
807	Alizarine Black SE SET SX SXT (M)	198,491
	Patent Alizarine Black	61,500
862	Alizarine Black B 3B	123,684

As these figures include Cassella importations they are probably subject to a deduction of at least 20,000 lbs. for acid black sold in this market as Alizarine Black 4B.

180	Eriochrome Blue Black B (G)	43,880
181	Palatine Chrome Black 6BX	65,658
183	Eriochrome Black T conc. (G)	129,550
184	Eriochrome Black A (G)	96,570
157	Diamond Black PV P2B PVT (By)	285,047
275	Diamond Black	351,582
	Salicine Blacks (K)	177,203
	Chrome Fast Blacks (Ber)	76,451
185	Anthracene Chrome Blacks (C)	51,577
265	Sulphoncyanine Black	69,590
	Nerol B 2B BL 2BL VL (Ber)	65,441
	Alphanol Blacks (C)	30,189
	Acid Alizarine Gray (M)	7,554

(2) Acid Colors.

Reference has already been made to the acid-dyeing Alizarines and to the one-dip colors of exceptional fastness to fulling, but the ordinary acid dyestuffs which have this useful property are given below. Standing somewhat apart from this group are the Eosines with importations of 128,160 lbs., exclusive of the Eosine made here from German intermediates. Acid Rhodamines are also included but the Rhodamines are given with the Basic Colors. In detail the importations are:

		Pounds
587/9	Eosine	59,044
	Bromofluoresceic Acid (M)	38,000
	Acid Eosine (B)	17,499
592	Erythrosines (M)	4,449
593	Phloxines	3,264
595	Rose Bengales	3,631
585	Uranine	2,273
	Anthrosines (B)	3,360
	Acid Rhodamines (B)	7,038

In *Red,* excluding the above mentioned Eosine group, the importations are 1,650,000 lbs., of which 818,249 lbs. are Scarlet. The most impotrant colors are:

		Pounds
524	Acid Magenta	19,098
147	Azofuchsine 6B	28,704
	Guinea Bordeaux B BL 6B (Ber)	23,252
672	Azo Carmine GX (B)	17,500
	Wool Cerise SR (K)	16,038
112	Bordeaux B	44,521
168	Amaranth	88,571
66	Amido Naphthol Red 2B (M)	36,000
	Azo Rhodine 2B (S)	10,108
42	Amido Naphthol Red G	4,999
64	Azo Acid Magenta G (M)	10,000
146	Azofuchsine G (By)	17,819
40	Chromotrop 2R (M)	5,000
57	Chromotrop S DW (M)	7,500
	Brilliant Carmines (B)	6,383
249	Croceine Scarlet 10 B (By)	7,275
163	Azo Rubine etc	251,477
	Carpet Reds (K)	15,445
161	Fast Red A	52,036
	Brilliant Lanafuchsine (C)	11,289
64	Lanafuchsine SG etc	80,659
	Acid Reds (K)	30,099
